**QUALITATIVE AND QUANTITATIVE ANALYSIS ON SOME  
CHARACTERISTICS OF CIRCULAR SECTOR MICROSTRIP ANTENNAS**

**BY**

**SUDIP KUMAR GHOSH**

Department of Electronics & Communication Engineering

Name of Supervisor : Prof. Sudipta Chattopadhyay

Name of Joint Supervisor : Prof. L. Lolit Kumar Singh

Submitted

In partial fulfillment of the requirement of the Degree of Doctor of Philosophy in  
Electronics and Communication Engineering of Mizoram University, Aizawl

**Department of Electronics and Communication  
Engineering**

School of Engineering and Technology

**MIZORAM UNIVERSITY**

*(A Central University)*

Tanhril, Aizawl - 796 004, Mizoram

---

**CERTIFICATE**

This is to certify that the thesis entitled “**Qualitative and Quantitative Analysis on Some Characteristics of Circular Sector Microstrip Antennas**” submitted to Mizoram University for the award of the degree of **Doctor of Philosophy Electronics and Communication Engineering** by **Sudip Kumar Ghosh**, Ph.D Registration No. **MZU/Ph.D/1179** of **23.04.2018**, is Ph.D scholar in the Department of Electronics and Communication Engineering, under our guidance and supervision and has not been previously submitted for the award of any degree in any Indian or foreign University. He has fulfilled all criteria prescribed by the UGC (Minimum Standard and Procedure governing Ph.D. Regulations). He has fulfilled the mandatory publication (Publication enclosed) and completed Ph.D. course work. It is also certified that the scholar has been admitted in the Department through an entrance test, followed by an interview as per UGC Regulation of 2016.

Date: February, 2022

Place : Aizawl

**(February 2022)**

**DECLARATION**

**I, Sudip kumar Ghosh**, hereby declare that the subject matter of this thesis entitled “**Qualitative and Quantitative Analysis on Some Characteristics of Circular Sector Microstrip Antennas**” is the record of work done by me, that contents of this thesis did not form basis of the award of any previous degree to me or to do the best of my knowledge to anybody else, and that the thesis has not been submitted by me for any research degree in any other University/Institute.

This is being submitted to the Mizoram University for the degree of Doctor of Philosophy in **Electronics and Communication Engineering**.

Date:

(Sudip Kumar Ghosh)  
**Candidate**

(Prof. Sudipta Chattopadhyay)  
**Supervisor**

(Prof. N. P. Maity)  
**Head of the Department**

(Prof. L. Lolit Kumar Singh)  
**Joint Supervisor**

## Acknowledgement

I would like to express my sincere, heartfelt gratitude and indebtedness to my supervisors, **Prof. Sudipta Chattopadhyay**, Professor, Department of Electronics and Communication Engineering, Mizoram University, Aizawl, Mizoram and joint supervisor, **Prof. L. Lolit Kumar Singh**, the Dean of School of engineering and Technology, Mizoram University, Aizawl, Mizoram, for their support, effective guidance, timely motivation, constant encouragement and valuable suggestions throughout the course of this research work. I am also thankful to **Prof. N. P. Maity**, Head of the Department of Electronics and Communication Engineering, Mizoram University, Aizawl, Mizoram. I am grateful to **Dr. Abhijyoti Ghosh**, Assistant professor, Department of Electronics and Communication Engineering, Mizoram University, for constant support and encouragement and planning during the course of research work.

I thank my doctoral committee members **Dr. Reshmi Maity** and **Dr. Achinta Baidya** for their suggestions and comments that have enabled me to complete the research work.

I extend my sincere gratitude to the **Prof. (Dr.) P. K. Adhvaryu**, Director Siliguri Institute of Technology, Management and Head of the Department of Electronics and Communication Engineering, Siliguri Institute of Technology, Siliguri, for having encouraged me and provided the facilities for carrying out the research work. I also wish to thanks **Dr. Gautam Das**, **Ms. Dia Ghosh** and **Mr. Subhamay Sarker** for constant support and help.

I wish to record my deep sense of gratitude to my family, **Mr. Panchanan Ghosh** and **Ms. Malati Ghosh** and **Ms. Sarbani Mondal** for their encouragement and moral support. I extend my whole heartedly thanks to my wife, **Mrs. Paramita Poria (Ghosh)** and my son, **Mr. Satyaki Ghosh** for their uninterrupted support, love, prayers and sacrifice during the course of research work.

I would like to convey special thanks to one and all those who have directly or indirectly extended their helping hand in this endeavor.

Finally, I am grateful to the Lord Almighty for giving me the opportunity,

knowledge and strength that had lead me successfully to the end of this research work.

**SUDIP KUMAR GHOSH**

# CHAPTER

# 1

## Introduction

### 1.1 Introduction

In the present era, and future inclination of development of wireless communication has become popular and prolific than ever before with advancement of civilization. With the technological advancement of various wireless communication technologies such as 5G, LTE, WiFi, Li-Fi, RFID, 6LoWPAN etc. have greatly boosted the potential capabilities of internet of things (IoT) and made it more user friendly than ever. So, the research on wireless communication technology attracts the new researchers to develop these emerging technologies with integration of microstrip antenna (MA) due its plentiful advantages like light weight, low profile, small size and ease in implementation on curved surface. The concept of microstrip antenna was begun in 1953 by Deschamps [1]. The basic structure of a microstrip antenna (MA) is parallel plate conductor which composed of a very thin conducting material strip (patch) printed on ground plane & dielectric (substrate) in between. The shaped of Patch conductor can have any geometrical shape; it is made of copper or gold etc. The conventional geometry of a widely used microstrip antennas in form of circular patch has been depicted in Fig. 1.1. The value of relative dielectric constant ( $\epsilon_r$ ) of the substrate is generally taken as low in the span of 2 to 10 i.e. Polytetrafluoroethylene (PTFE  $\epsilon_r = 2.33$ ), flame retardant (FR4  $\epsilon_r = 4$ ) materials etc.

Two decades later Howell [2] demonstrated theoretical and practical design method in perspective of dipole antenna. Thereafter Munson [3] implemented a

microstrip as an Omni-directional antenna for application of aircraft / airborne system.

**Fig. 1.1** Basic structure of circular microstrip antenna (a) Top view (b) Side view.

### **Advantages and Limitations of MA**

The microstrip patch antenna has numerous advantages like ease to printed on the circuit board, accurate patch area, low profile, not bulky in size, in view of this flexibility it can be placed to any curve surface and any shape of structure can be achieved through molding it. Plenty number of MA can be manufactured due to less expensive and effortless fabrication. This microstrip antenna are also serve to modern wireless communication system as it is easily compatible to the technology related to the microwave monolithic integrated circuit (MMIC) and opto electronic integrated circuit (OEIC). It is equally applicable to the linear, circular polarisation

and also support any kind of frequency operation like dual , triple frequency etc. Large area can be covered with in limited space by making array configuration. It is easily mounted on the stiff surface due to robustness. The microstrip patch antenna has some limitations besides many advantages discussed below.

Compare to the conventional antenna, it has following disadvantages like inbuilt low bandwidth and low gain limited to 2-5 dBi only. Improvement of bandwidth is restricted to 1-5% after given an extra effort. The efficiency of the conventional MA is not promising and to achieve good polarisation purity , excess effort need to pay. Power handling capability is also low. Extra amount of radiation comes from feed and junction which enhances additional complexity.

Following limitations can be overcome by using thicker substrates, etching slots in patch surface, addition to parasitic patches on the top of the patch area or introducing aperture coupled stacked patch antennas.

The theoretical analysis and practical verification of different geometry MA gets attracted to the research community that came into sight in between [4]-[14]. The wonderful literature on microstrip antenna was first published [15] in 1980 as a hand book which covers multiple aspects on MAs of different geometry. Followed by [15] James, Hall and Wood [16] brought a new edition on design aspect of microstrip antenna in 1981. The fundamental Antenna theory and multiple design issues of microstrip antenna were well covered by Balanis [17] in 1997. Different kind of design and analysis including broad banding and new feed mechanism has been reported in [18] by R. Garg et.al. In the following section 1.2 the basic feeding mechanism of MA has been described. Some elaborate method of feeding mechanism has been reported in [19]-[28].

This chapter deals with the different feeding techniques of MA in section 1.2, The radiation characteristics of MAs have been discussed in section 1.3, Choice of patch geometry has been described in section 1.4. Finally, the preface of the dissertation has been described briefly in section 1.5.

## **1.2 Different Feeding Techniques**

When MA get excited by applying any certain voltage signal to the patch. It starts radiating and maximum radiation come out from its edge and goes in the broadside

direction and no radiation (ideally) in the end fire direction. To get efficient radiation, the MA can be generally fed by direct (contact) or indirect (non-contact) way. Co-axial fed, microstripline fed, proximity coupled fed and aperture coupled fed is most popular out of contact or non-contact method.

### 1.2.1 Co-axial Feed Technique

In this technique, the probe conducting material is connected through the dielectric to the radiating patch. This is very widely used technique, where probe can be placed at anywhere of the patch to match  $50\ \Omega$  impedance. This is easy to fabricate and match impedances.

**Fig. 1.2** Co-axial feed circular microstrip antenna (a) top view (b) side view

This technique suffers in narrow bandwidth around 2-3% and high cross

polarization radiation due to asymmetries in feed position and feed induced spurious radiations. Also, coaxial feed introduces large inductance in case of thick substrates. In the Fig. 1.2 co-axial probe fed microstrip antenna in top view and side view has been shown. Where ' $a$ ' is the radius of circular patch.

### 1.2.2 Microstripline Feed Technique

In this method, a strip of conducting material is joined directly to the edge of the patch as shown in Fig. 1.3. It is one of the common feeding techniques. To achieve better impedance matching, the controlling of inset cut position movement to the patch is desire only. It is easy to fabricate, simple to model and analyze. However, the feedlines increase spurious radiations from antenna. With increase in substrate thickness, surface waves are increased in antenna. Also, such feed line contributes in exciting higher order modes in antenna and enhancing cross polar radiation from antenna. Further, it has low bandwidth around 2-3%.

**Fig. 1.3** Microstripline feed circular printable antenna.

### 1.2.3 Proximity Couple Feed Techniques

There are two dielectric material substrate 1 ( $\epsilon_{r1}$ ) and substrate 2 ( $\epsilon_{r2}$ ). Patch is mounted on the 2<sup>nd</sup> dielectric, the feedline is placed in between the two dielectric.

The ground plane is placed below 1<sup>st</sup> dielectric material. In this type of method, microstrip line conducting material does not connected directly to the patch. That's why this feeding technique is known as electromagnetic coupling which is shown in Fig. 1.4. The advantage of having this type of feeding technique is that provides large bandwidth around 13% and eliminates unwanted spurious radiation. Fabrication is quite difficult due to which this technique becomes expensive.

**Fig. 1.4** Proximity coupled feed circular printable antenna.

#### **1.2.4 Aperture Coupled Feed Technique**

It is also non-contacting feed technique as shown in Fig. 1.5, where the ground plane is sandwiched by two substrates. There is microstrip line in 1<sup>st</sup> substrate and patch is grown on the 2<sup>nd</sup> substrate. The slot is design on ground plane through which the line is coupled to get radiation. The advantage of this symmetrical design is that the two dielectrics can be selected separately to optimize the patch radiation and lower cross-polarization. This technique avoids use of soldering and minimizes the chance of leakage current from feed. It also reduces the reactance of feed and also exhibits wide bandwidth in comparison with other feeding techniques. However, the fabrication is difficult compare to all other technique as structure is multilayer. Also, back radiation increases in such structures.

**Fig. 1.5** Aperture coupled feed circular printable antenna.

### 1.3 Radiation Characteristics

Multiple radiation characteristics like co-polarization gain, beam width, co-polarization radiation to cross polarization radiation isolation (polarization purity) of microstrip antenna has been studied in [29]-[68], where techniques like dielectric cover over the patch [29], laminated ground plane [30], LiTiMg Ferrite substrate [31], air substrate [32], electromagnetic band gap surface [33] is utilized to improve radiation performance of MA. The use of Green's function [34], finite ground plane [35], and neuro-spectral computation approach [36] have been reported to analyze the radiation characteristic of MA. Spiral geometry size of circular microstrip antenna (CMA) [37] and superstrates loaded CMA [38] have been employed to increase the gain and half power beam width of the antennas. The improvement of gain by employing different method has been reported in [39]-[58]. Out of them, the use of superstrates on microstrip antenna [39]-[40], introduction of air gap [41]-[42] have been investigated successfully. Around 5-7 dBi gain has been achieved by surface waves suppression using electromagnetic band gap (EBG) structure in [43], photonic band gap (PBG) structure in [44] and partially etched substrate in [45]. The gain of the microstrip antenna can be also enhanced through

defected on the ground surface (DGS) that has been reported in [46]-[47] and slotted ground plane in [48] which yields 7.2-9.2 dBi gain.

The different techniques has been evoked to improve the gain of circular microstrip antenna that come into views in [49]-[56], such as in [49]-[50] aperture couple based slot loading technique, in [51]-[53] shorting pin. The employment of frequency selective surface [54], multishaped substrate [55] in MA reveals the techniques of gain enhancement of such antennas. Maximum 9 dBi gain with 90% efficiency has been achieved in above mentioned literatures. However, these investigations fail to address the improvement in polarization purity of MA. Polarization purity is another important part of radiation characteristics, that has been studied and improved in various ways in [56]-[77]. Suspended path with dual feed [56], Meander line feeding [57]-[58], W and U shaped ground plane [59], [60] have been reported which yields 18-20 dB polarization purity. The most effective techniques to improve polarization purity till date are the employment of DGS [61]-[71], defected patch structure [72]-[74], and shorting stripes or post [75]-[77] with MAs which can yield around 20 dB of polarization purity.

#### **1.4 Choice of Patch Geometry: A Survey**

Several types of patch geometries such as rectangular, circular, triangular, octagonal, hexagonal etc can be useful as radiating element of MA. All these geometries except rectangular and circular are complex in nature and there are no available well established theories which can be adopted easily in the industries for batch production. Therefore, to develop the MA in more cost effective way, rectangular and circular geometries are very popular and preferred [78]. Also industry prefers such rectangular and circular geometry for its simple design and ease to mount the antenna inside the device without much change in the device periphery. Again, the trouble shooting can be easily done due its wide versatility and concrete established theory with promising characteristics. The thorough investigation with such simple rectangular and circular geometries have gained potential demands to the researchers and finds plentiful applications in modern wireless technologies in last two decades. In this context, large number of traditional geometries such as rectangular and circular MAs, have been widely investigated,

explored [79]-[84] and implemented [85]-[90].

The resonance frequency of rectangular microstrip antenna (RMA) can be written as

$$f_r = \frac{c}{2L\sqrt{\epsilon_r}} \quad (1.1)$$

where,  $L$  is the length of the patch,  $\epsilon_r$  is the dielectric constant,  $c$  is the velocity of the light.

While the same for circular microstrip antenna (CMA) is

$$f_r = \frac{1.84c}{2\pi a\sqrt{\epsilon_r}} \quad (1.2)$$

where,  $a$  is the radius of the patch,  $\epsilon_r$  is the dielectric constant and  $c$  is the velocity of the light.

Comparison of equation (1.1) and equation (1.2) reveals that the required radial dimension of CMA is smaller than RMA. Therefore, in the present scenario of miniaturization, CMA can be more effective in tinny electronic devices.

However, more miniaturization in antenna geometry is always preferred in the present era where, the tiny wireless communication devices are most effective and popular. Infact, in the present era, most of the hand held wireless communication devices are budding towards tininess and multi functionality for compatibility with MMIC.

Therefore, the occasions are there where the geometry other than the conventional rectangular and circular geometries is favorable.

Circular sector microstrip antenna (CSMA) is very advantageous where the space is the key factor to organize a patch with conventional geometry. In fact, around 60% of patch area reduction can be achieved by the suitable choice of sector angle for a particular resonant frequency compared to conventional circular patch geometry. Here, the through and elaborate investigation on CSMA is very much required also challenging to the antenna researchers. Therefore, through investigation on CSMA is the modern state- of –art research field of antenna engineering. The CSMA is highly usable as it requires less space compare to conventional circular patch antennas. Therefore, an accurate analysis of CSMA is one of the main concerns in the printed antenna research field. The formulation of resonance frequency ( $f_r$ ) of CSMA based on conventional cavity model was first reported in [89]-[90]. Followed by them, further attempts were made to estimate the dominant mode and its resonance

frequency in [91]-[92]. However, in [92], radiation pattern of CSMA is reported based on simulation results. The radiation pattern of CSMA with  $60^\circ$  sector angle was reported in [92]. However, [89]-[92] predicts the resonance frequency of CSMA with large error of around 2.5% between simulation and quantitative estimation. The resonance frequency with  $60^\circ$  and  $90^\circ$  sector angle has been investigated in [91]-[96] through simulation and around 3.8% error has been revealed in predicting resonance frequency. Furthermore [91]-[92] fails to determine the accurate dominant mode of CSMA. As such the dominant mode of CSMA depends critically on the sector angle. The study of resonance frequency and radiation field of CSMA had been presented in [93]-[96] based on simulation. The array structure with CSMA for the C and X band was investigated and the effect of element number in the array was reported in [95]. A simulation study of CSMA with  $70^\circ$  sector angle for CSMA was reported in [96]. Some newer applications of CSMA on broadband, dual polarized, circularly polarized antenna have been reported in [97]-[100]. In [97] comparatively large sector angles  $270^\circ$  CSMA and  $320^\circ$  CSMA have been investigated to improve the gain around 7 dBi and to achieve bandwidth of around 500 MHz. Proximity fed CSMA with multiple sector angles  $340^\circ$ ,  $350^\circ$ ,  $355^\circ$  have been studied for broad banding more than 700 MHz in [101]. Moreover, application of dual mode wide banding and dual port CSMA has been reported in [102]-[103]. In [102] dual mode of  $270^\circ$  CSMA has been excited simultaneously and evolve bore sight gain of 8.1 dBi. The antenna has been minimized about 44% comparison to conventional CMA without improving the gain of CSMA and the cross pole comparison got more than 20 dB in [103]. Further, dual band meta loaded semicircular CSMA with operating frequency 4.1 GHz has been reported in [104]. The measured gain of this antenna is 5.82 dBi with bandwidth of 114 MHz only. Furthermore, the application of broad banding of  $120^\circ$  and  $270^\circ$  sectoral patch and circular polarization with the help of CSMA is documented in [105]-[109]. In [105] a compact size of  $109^\circ$  CSMA has been reported for application of Ku band. This antenna exhibits 6.57 dBi simulated gain with 5 dB cross polarization only. To achieve circular polarization, the study of  $65^\circ$  sectoral patch antenna has been reported in addition with arc shape slots and slits structure in [106]. Further,  $270^\circ$  sectoral patch with rectangular cut slot has been reported in [107], which yields 8.5 dBi peak gain. The study of proximity fed  $120^\circ$

CSMA has been reported for broad banding and yields broadside peak gain of about 9.2 dBi in [108]. The comparison between RMA and the CSMA in C band array has been reported in [109] but gain of this antenna is quite low and it is around 5 dBi. Nevertheless, all these investigations were initiated through simulation followed by measurements.

The above mention reports, mainly discuss the CSMA with specific sector angle and mostly in intuitive way. They failed to draw accurate theoretical and analytical studies which are very much required to understand the structural behavior of CSMA in details for the design engineers working with CSMA. Therefore, all this lacuna of earlier studies should be investigate elaborately to understand the exact behavior of CSMA.

## **1.5. Preface of the Dissertation**

In the dissertation, improvement of some input and output characteristics of CSMA have been investigated theoretically and implemented practically.

This antenna has been attracted to the antenna community and manufacturer in this modern age due to its compact size requirement compare to conventional geometry like circular patch antenna. So as to prepare modern hand held wireless device, less size of the antenna is being required to keep the associated circuitry besides the antenna. CSMA is highly demandable in this context but accurate resonance frequency and lowest order mode determination of this antenna is still lacking.

In chapter 2, the resonance frequency has been analyzed accurately. The effect of the feed location of the modes has been investigated further to determine the lowest order dominant mode with variation of substrate height, substrate permittivity and air gap. The improved computer aided design (CAD) has been formulated which makes the CSMA more promising than ever before. Modified cavity model has been introduced to determine the lowest order modes in CSMA.

In Chapter 3, the feed-probeposition for excitations of desire mode has been investigated and presented theoretically and verified experimentally. To find a proper feed location for exciting a particular mode in a CSMA, the appropriate theoretical formulation is another basic requirement. In this context no well established theoretical formulation for exciting a dominant mode of a CSMA is available till

date. Therefore, the determination of modes of a CSMA as a function feed location has been investigated and a new theoretical approximation technique has been projected based on maximum E/H ratio in this chapter to excite a specific mode.

Indeed, CSMA with different range of sector angles has been classified and discussed scientifically by the relation of E/H ratio. A particular range of  $|E/H|$  has been prescribed on which a particular mode can be excited. Moreover, a range of feed location has been approximated across which a particular mode can be excited if probe is placed.

Previous two chapters have been concentrated only the investigation of input characteristics. So the radiation characteristics and gain of this antenna have been given emphases to explore the performance of the antenna in some extent. The Gain of this antenna is generally low (7.1 dBi) that has been improved (9.9 dBi) by introduce an air in the substrate. The quick hand empirical formula also has been prescribed in this chapter.

In chapter 4, the complete design guideline has been prescribed for the specific application. The behavior of CSMA is generally varied with sector angles due to its asymmetric structure. So numerous number of sector angles are there. Thus selection of sector angles as a function of operating mode and frequency & miniaturization has been described for better selection and comprehensive guideline has been prescribed in this chapter.

In chapter 5, CSMA of  $180^\circ$  sector angle has been considered for investigation in view of the replacement of CMA. The minimization of patch area is advantageous around 50% as compare to circular microstrip antenna but co-pole (CP) to cross pole (XP) isolation is not satisfactory. Therefore to minimize XP radiation in this chapter, the patch area has been defected judiciously. Further the effect of ground plane variation also studied.

Finally in chapter 6, a conclusion of complete work has been presented and the best choice of sector angle antenna has been identified which can be used for all perspective such as industrial applications along with research and future application.

## **Circular Sector Microstrip Antenna: Determination of Accurate Modes Using Modified Cavity Model**

### **2.1 Introduction**

In the modern era of wireless communications, the design and analysis of miniaturized and multifunctional antennas of different geometries continue to be the focus of state-of-the-art research. In this scenario, the most common geometries of microstrip antennas (MAs), such as rectangular and circular, have been extensively studied, analyzed and implemented for at least the last three decades as discussed in chapter 1. However, in various practical wireless applications, radiators should be conformally mounted onto the previously existing structures, where space limitation is a crucial problem. In such applications, a circular sector microstrip antenna (CSMA) is highly advantageous because it requires less space than a conventional patch antenna of common geometries. Approximately more than 50% patch area reductions can be achieved with particular sector angles, compared with a conventional circular MPA. Therefore, an accurate analysis of CSMA is a priority in the present scenario of printed antenna research. In this context, a limited number of analyses [1]-[5] have been reported in which the computation of the accurate resonant frequency of CSMA with arbitrary sector angles has been dealt with. The formulation of the resonant frequency of a CSMA based on the cavity model was first reported in [1]. The electric field beneath the patch as well as the eigen functions of those antennas were also presented in [1]. In [2], a generalized transmission line modeling was used for computing the resonant frequency of a CSMA. However, the effect of fringing fields, which should be considered for the

accurate estimation of the resonant frequency of a CSMA, was not included in [1]-[2].

Recently, the theoretical and experimental analyses of CSMA have been reported in [3]-[4]. In these works, the authors introduced the idea of fringing fields for computing the effective dimension of the patch required for calculating the resonant frequency of the antenna. However, the resonant frequency of the antenna could not be accurately predicted; and the dominant mode of CSMA has been assumed to be similar to that of a conventional circular patch ( $TM_{11}$ ), regardless of the sector angle in [3]-[4]. Nevertheless, the dominant mode of a CSMA should differ for different cavity dimensions (i.e., for changes in the sector angle) to satisfy the boundary conditions of electromagnetic fields beneath the patch.

Therefore, the identification of the mode of a CSMA with different sector angles is inappropriately reported in [3]-[4]. Moreover, the validation of the theories presented in [3]-[4] in terms of varying antenna parameters (such as substrate thickness, dielectric constant and air gap height) is not included. Furthermore, the higher modes were not investigated in those reports. In [5], Bhattacharya et al have computed the resonant frequency of the CSMA following the cavity model; however, they failed to identify the accurate dominant mode of the CSMA and predict its accurate resonant frequency. The study of the radiated field, resonant frequency and polarization of the CSMA was presented in [6]. The array structure with CSMA for the C and X band was investigated and the effect of element number in the array was reported in [7]. A simulation study of CSMA with  $70^\circ$  sector angle for CSMA was reported in [8]. Recently, some newer applications of CSMA have been reported in [9]-[11], however, accurate dominant modes of the antenna were not emphasized in these reports. The resonant frequencies in these studies were based only on simulations. Therefore, neither the lowest order dominant mode, nor the corresponding resonant frequency of the CSMA has been accurately determined in these previous investigations. Furthermore, in the study of a CSMA, the introduction of an air gap between the substrate and the ground plane, which offers the tunability of microstrip structures for rectangular and circular geometries, is very important [12]-[13].

(d)

(e)

**Fig. 2.1** Schematic representation of coax fed circular sectorial microstrip antenna (CSMA) (a) top view, (b) side view, some of the fabricated prototypes (c)  $45^\circ$  sector angle, (d)  $90^\circ$  sector angle, (e)  $60^\circ$  sector angle respectively.

However, the role of an air gap in the resonance behavior of the CSMA needs further investigation. To eliminate the lacunae of earlier works, the modal fields of the dominant as well as higher order modes of numerous CSMAs with different sector angles have been thoroughly studied. In this paper, an improved, accurate and comprehensive computer-aided design formulation for accurately determining the resonant frequency of a CSMA is proposed. The proposed formulation accurately

estimates the dominant and higher mode resonances in a CSMA with and without an air gap between the substrate and the ground plane. The mathematical derivations are based on the modified cavity model along with the accurate estimation of the effective permittivity and the effective antenna dimensions. The complete theory is presented meticulously in this paper for developing a concrete physical basis for the observed phenomenon. No published work that presents the variation of the resonant frequency of a CSMA with substrate thickness, air gap height, substrate permittivity, and the radial dimension of the antenna is available till date. Considering all the above-mentioned factors, the resulting variations of resonant frequencies as a function of the aforementioned parameters, have been included in the present study.

The theoretical formulation for the resonant frequency of a CSMA has been presented in section 2.2. The resonant frequency of a CSMA with varying sector angle and dielectric thickness is analyzed and a comprehensive and closed-form formulation is proposed in section 2.2.1. Therefore, an efficient equivalence relation is established and utilized for calculating the effective dimension of the patch has been described in section 2.2.2. Subsequently, the calculation of the effective dielectric constant of a CSMA has been presented in section 2.2.3. In section 2.3, the proposed theory has been validated against our simulation, the measurement data available in the literature, and our own measurement results. The resonant frequency of a CSMA as a function of substrate thickness, radial dimension of a patch and sector angle as well as the versatility of the present theory in determining the accurate higher order modes of CSMA for different sector angles are included in section 2.3. Section 2.4 contains the conclusions derived from the findings of the present work.

## 2.2 Theory

A coaxially fed CSMA with radial dimension  $a$ , printed on a substrate ( $\epsilon_r$ ) of thickness  $h_1$  with an air gap of height ( $h_2$ ) on the ground plane is shown in Fig. 2.1. The height of the air gap varies from zero to a certain finite value. The antenna is fed at a distance  $\rho_c$  from the apex of the conical shape as shown in Fig. 2.1 (a) using a coaxial probe. Some of the fabricated prototypes are shown in Fig. 2.1 (c). To calculate the resonant frequency of CSMA accurately, first the cavity model for

conventional circular patch has been utilized under the restriction of modified boundary conditions, as will be explained in section 2.2.1. This, in fact, provides a basic estimation of the resonant frequency of CSMA, with and without air gap. The fringing of the electric fields, at the edges of the patch, increases the effective dimension, which is accounted for in terms of  $a_{eff}$ . Indeed, this parameter needs to be determined precisely for accurate determination of antenna characteristics. Therefore, computations of effective dimension of the antenna and the effective dielectric constant are significant issues, which are discussed in section 2.2.2 and section 2.2.3.

### 2.2.1 Modified Cavity Model

Because of the narrowband resonant characteristics of their open radiating structures, microstrip antennas, can be viewed as lossy cavities. From this view point, cavity model is a very natural choice to analyze the modal fields of such antennas [14]. Classical description of using cavity model to determine the modal fields of conventional rectangular and circular patches can be found in [27]. Recently, cavity model analysis of shorted patch structure has been reported in [15]. In a very recent paper [16], exploitation of cavity model is documented for gain and bandwidth enhancement of a rectangular patch antenna.

**Fig. 2.2** The cavity model for CSMA.

The top and bottom walls (at  $z = 0$  and  $h$ ) are perfect electric conductors (PEC), and three side walls are perfect magnetic conductors (PMC). Here, the normalized fields within the dielectric substrate (between patch and ground plane) can be determined accurately by treating the region as a cavity, bounded above and below by electric conductors (top and bottom plates, respectively) and along the periphery by magnetic walls. In the case of circular sector antenna, a modified cavity has been germinated whose top and bottom walls are perfect electric conductors (PEC), and the three side walls are perfect magnetic conductors (PMC).

The modified cavity model (MCM) is shown in Fig. 2.2.

The vector potential  $A_z$  must satisfy the homogeneous wave equation [17]

$$\nabla^2 A_z(\rho, \phi, z) + k^2 A_z(\rho, \phi, z) = 0 \quad (2.1)$$

where,  $A_z$  is given by [17] as

$$A_z = B_{mnp} J_m(k_\rho \rho) [A \cos(m\phi) + B \sin(m\phi)] [\cos(k_z z)] \quad (2.2)$$

Therefore, the fields will be given by

$$\left. \begin{aligned} E_\rho &= -\frac{j}{\omega\mu\epsilon} \frac{\partial^2 A_z}{\partial \rho \partial z} \\ H_\rho &= \frac{1}{\mu} \frac{1}{\rho} \frac{\partial A_z}{\partial \phi} \\ E_\phi &= -\frac{j}{\omega\mu\epsilon} \frac{1}{\rho} \frac{\partial^2 A_z}{\partial \phi \partial z} \\ H_\phi &= -\frac{1}{\mu} \frac{1}{\rho} \frac{\partial A_z}{\partial \rho} \\ E_z &= -\frac{j}{\omega\mu\epsilon} \left( \frac{\partial^2}{\partial z^2} + k^2 \right) A_z \\ H_z &= 0 \end{aligned} \right\} \quad (2.3)$$

Where  $\omega$ ,  $\mu$  and  $\epsilon$  are the frequency of the wave, permeability and permittivity of the medium respectively.

Based on the above equations, the resonant frequency of CSMA, with the widely used sector angles ( $\phi_0 = 180^\circ$ ,  $90^\circ$  and  $60^\circ$ ) is documented in the following sections.

Now, for the CSMA with arbitrary sector angle  $\phi_0$ ;

$$H_\phi = 0; (\rho = a, 0 \leq \phi \leq \phi_0^0; 0 \leq z \leq h) \quad (2.4)$$

$$H_\phi(\rho = a) = -\frac{1}{\mu} \frac{\partial A_z}{\partial \rho} = -\frac{1}{\mu} B_{mnp} J'_m(k_\rho a) [A \cos m\phi + B \sin m\phi] [\cos(k_z z)] = 0 \quad (2.5)$$

which signifies that,

$$J'_m(k_\rho a) = 0 \Rightarrow k_\rho a = \chi'_{mn} \Rightarrow k_\rho = \chi'_{mn} / a \quad (2.6)$$

where,  $J_m$  and  $J'_m$  are the Bessel functions of order  $m$  and its derivative respectively.  $\chi'_{mn}$  is the  $n^{\text{th}}$  zero of derivative of Bessel function of order  $m$ .

Again, the vanishing radial magnetic field boundary condition demands that,

$$\begin{aligned} H_\rho &= 0; (\phi = 0, 0 \leq \rho \leq a; 0 \leq z \leq h) \\ H_\rho &= 0; (\phi = \phi_0^0, 0 \leq \rho \leq a; 0 \leq z \leq h) \end{aligned} \quad (2.7)$$

Thus,

$$H_\rho(\phi = 0) = \frac{1}{\mu} \frac{1}{\rho} \frac{\partial A_z}{\partial \phi} = \frac{1}{\mu} \frac{1}{\rho} B_{mnp} J_m(k_\rho \rho) [-mA \sin m\phi + mB \cos m\phi] [\cos(k_z z)] = 0 \quad (2.8)$$

It is possible, if  $B = 0$

Now,

$$H_\rho(\phi = \phi_0^0) = \frac{1}{\mu} \frac{1}{\rho} B_{mnp} J_m(k_\rho \rho) [-mA \sin m\phi_0] [\cos(k_z z)] = 0 \quad (2.9)$$

It is possible, if

$$m\phi_0 = q\pi$$

$$m = \frac{q\pi}{\phi_0} \quad (2.10)$$

where  $q = 0, 1, 2, 3$ , and all positive etc.

Again, the tangential electric field boundary condition requires that

$$\begin{aligned} E_\phi &= 0; (z = 0, 0 \leq \rho \leq a; 0 \leq \phi \leq \phi_0^0) \\ E_\phi &= 0; (z = h, 0 \leq \rho \leq a; 0 \leq \phi \leq \phi_0^0) \end{aligned} \quad (2.11)$$

Therefore;

$$E_\phi(z = h) = \frac{j}{\omega\mu\epsilon} \frac{1}{\rho} B_{mnp} J_m(k_\rho \rho) k_z (-mA \sin m\phi) \sin(k_z h) = 0 \quad (2.12)$$

It is possible if,

$$k_z = \frac{p\pi}{h} \quad (2.13)$$

$$\text{Now, } k^2 = k_\rho^2 + k_z^2 \quad (2.14)$$

Where,  $k$  is the propagation vector and  $k_\rho$ ,  $k_z$  are the propagation vectors along radial ( $\rho$ ) and vertical ( $z$ ) directions.

The resonance frequency ( $f_r$ ) will be expressed as

$$f_r = \frac{1}{2\pi\sqrt{\mu\epsilon}} \sqrt{\left(\frac{\chi'_{mn}}{a}\right)^2 + \left(\frac{p\pi}{h}\right)^2} \quad (2.15)$$

Considering that the patch is on thin substrate, the zeroth order resonance frequency ( $f_r$ ) is

$$f_r = \frac{\chi'_{mn}}{2\pi a\sqrt{\mu\epsilon}} = \frac{\chi'_{mn}c}{2\pi a\sqrt{\epsilon_r}} \quad (2.16)$$

where,  $c$  is the free space velocity and  $\chi'_{mn}$  is the  $n^{\text{th}}$  zero of derivative of Bessel function of order  $m$ .

The parameter  $m$  is related to  $q$  by equation (2.10). The parameter  $n$ , in fact, denotes the number of radial variations, and  $q$  the number of circumferential variations.

Now considering the fringing effect around the patch periphery, the dimension  $a$  will be replaced by the effective dimension  $a_{\text{eff}}$ ; and the dielectric constant  $\epsilon_r$  by effective dielectric constant  $\epsilon_{\text{reff}}$ .

Thus equation (2.16) becomes

$$f_r = \frac{\chi'_{mn}c}{2\pi a_{\text{eff}}\sqrt{\epsilon_{\text{reff}}}} \quad (2.17)$$

The calculation of effective dimension  $a_{\text{eff}}$ , and the effective dielectric constant  $\epsilon_{\text{reff}}$  is shown in section 2.2.2 and section 2.2.3, respectively.

**Case-I:**  $180^\circ$  circular sector patch antenna ( $\phi_0 = \pi$ )

For semicircular patch,  $\phi_0 = \pi$ , and equation (2.10) becomes  $m = q$ . Thus, the possible values of  $m$  will be any positive integer greater than zero.

Following the roots of the derivative of Bessel function, the lowest value of  $\chi'_{nm} = 1.84$  occurs when  $m = 1, n = 1$ .

Therefore, according to equation (2.17), the lowest order resonant mode (dominant mode) of semicircular patch becomes  $TM_{11}$  and hence its frequency is

$$f_r = \frac{\chi'_{11}c}{2\pi a_{eff} \sqrt{\epsilon_{reff}}} = \frac{1.84c}{2\pi a_{eff} \sqrt{\epsilon_{reff}}} \quad (2.18)$$

**Case-II:**  $90^\circ$  circular sector patch antenna ( $\phi_0 = \pi/2$ )

For  $90^\circ$  circular sector,  $\phi_0 = \pi/2$ , and equation (2.10) becomes

$$m = 2q. \quad (2.19)$$

Thus, it is possible that  $m = 0, 2, 4, 6$ , etc.

Following the roots of the derivative of Bessel function, the lowest value,  $\chi'_{nm} = 3.05$ , occurs when  $m = 2, n = 1$ .

Therefore, following equation (2.17), the lowest order resonant mode (dominant mode) of  $90^\circ$  circular sector patch becomes  $TM_{21}$  and its frequency

$$f_r = \frac{\chi'_{21}c}{2\pi a_{eff} \sqrt{\epsilon_{reff}}} = \frac{3.05c}{2\pi a_{eff} \sqrt{\epsilon_{reff}}} \quad (2.20)$$

**Case-III:**  $60^\circ$  circular sector patch antenna ( $\phi_0 = \pi/3$ )

For  $60^\circ$  circular sector,  $\phi_0 = \pi/3$ , and equation (2.10) becomes

$$m = 3q \quad (2.21)$$

Thus, it is possible that  $m = 0, 3, 6, 9$ , etc.

Following the roots of the derivative of Bessel function, the lowest value,

$$\chi'_{nm} = 3.83, \text{ occurs when } m = 0, n = 1.$$

Therefore, following equation (2.17), the lowest order resonant mode (dominant mode) of  $60^\circ$  circular sector patch becomes  $TM_{01}$  and its frequency

$$f_r = \frac{\chi'_{01} c}{2\pi a_{\text{eff}} \sqrt{\epsilon_{\text{reff}}}} = \frac{3.83c}{2\pi a_{\text{eff}} \sqrt{\epsilon_{\text{reff}}}} \quad (2.22)$$

It may be noted that for  $60^\circ$  circular sector, no circumferential variation occurs when one radial variation exists beneath the patch. This can be proved pictorially also by observing the magnitude of the dominant mode electric field distribution on the surface of the patch (Fig. 2.3). This, in fact, produces a broadside radiation like circular patch with  $TM_{11}$  mode, but with lower gain. The gain can be enhanced by introducing a cavity beneath the patch as in [18] or by changing the substrate permittivity.

Suitable utilization of equation (2.3) reveals that, for a circular sector patch, the fields are

$$\left. \begin{aligned} E_\rho &= 0; E_\phi = 0; H_z = 0; \\ E_z &= B_{mnp} A \cos(m\phi) J_m(k_\rho \rho) \cos(k_z z) \\ H_\rho &= \frac{1}{\mu \rho} B_{mnp} J_m(k_\rho \rho) (-mA \sin m\phi) \cos(k_z z) \\ H_\phi &= -\frac{1}{\mu} B_{mnp} A \cos(m\phi) J'_m(k_\rho \rho) \cos(k_z z) \end{aligned} \right\} \quad (2.23)$$

Thus, in the dominant  $TM_{01}$  mode, the field components for  $60^\circ$  circular sector patch, are as follows:

$$\left. \begin{aligned} E_\rho &= 0; E_\phi = 0; H_z = 0; H_\rho = 0 \\ E_z &= B_{010} A J_0(k_\rho \rho) \cos(k_z z) \\ H_\phi &= -\frac{1}{\mu} B_{010} A J'_0(k_\rho \rho) \cos(k_z z) \end{aligned} \right\} \quad (2.24)$$

Fig. 2.4 confirms the existence of only two field components beneath the patch for the dominant mode ( $TM_{01}$ ), for  $60^\circ$  circular sector. This further corroborates the fact that  $TM_{01}$  is the dominant mode for  $60^\circ$  circular sector.

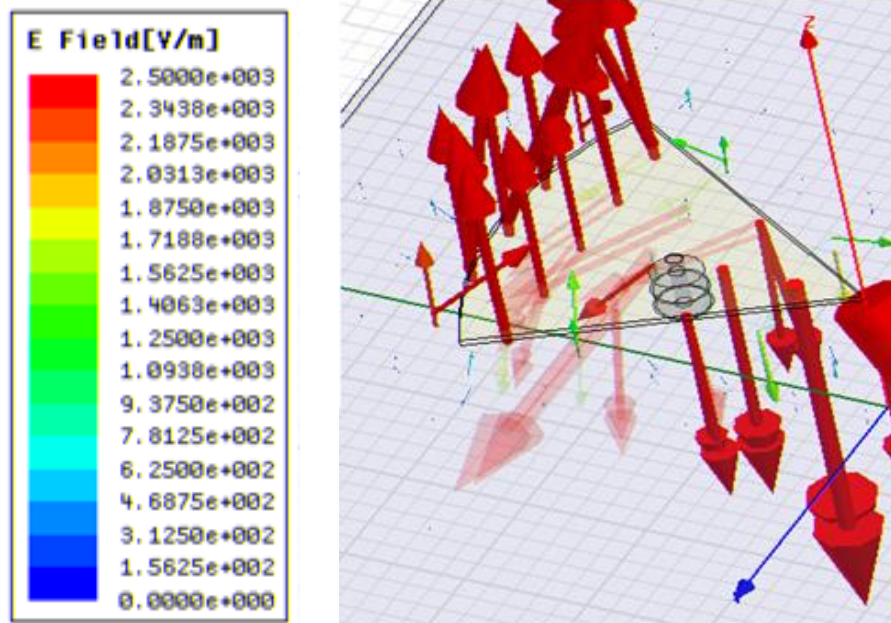

It may be noted that the electric field component does not vary with  $\phi$ , as can be seen from equation (2.24) and from Fig. 2.3.

Hence, in the dominant mode of CSMA (for  $60^\circ$  sector angle), only two field components exist, namely  $E_z$  and  $H_\phi$ . As all microstrip patch structures are fabricated

on a thin substrate, the variation along  $z$  direction is not considered. Therefore, the variations of  $E_z$  and  $H_\phi$  components of the dominant  $TM_{01}$  mode are dependent mainly on  $J_0(k_\rho \rho)$  and  $J'_0(k_\rho \rho)$ , respectively. The variations of  $J_0(k_\rho \rho)$  and  $J'_0(k_\rho \rho)$ , as a function of  $\rho$ , ensure that  $E_z$  becomes maximum at  $\rho = 0$ ,  $\rho = a$  and minimum near about the centre. On the contrary,  $H_\phi$  becomes maximum near the centre and minimum near the edges ( $\rho = 0$  and  $\rho = a$ ).

**Fig. 2.3** Electric field magnitude over the patch surface of CSMA (for  $60^\circ$  sector angle) for the dominant  $TM_{01}$  mode ( $f = 3.76$  GHz). Parameters:  $a = 30$  mm,  $h_1 = 1.575$  mm,  $h_2 = 0$ ,  $\epsilon_r = 2.33$ .

(a)

**Fig. 2.4** Field components of CSMA (for  $60^\circ$  sector angle) for the dominant  $TM_{01}$  mode ( $f = 3.76$  GHz) (a)  $z$  component of electric field, (b)  $\phi$  component of magnetic field. Parameters:  $a = 30$  mm,  $h_1 = 1.575$  mm,  $h_2 = 0$ ,  $\epsilon_r = 2.33$ .

## 2.2.2 Calculation of Effective Dimension

The effective dimension of the antenna ( $a_{eff}$ ) can be calculated according to [19], thus

$$a_{eff} = a\sqrt{(1 + q_1)} \quad (2.25)$$

Where  $q_1$  is the fringing factor, which can be obtained from [19]. On the other hand, the calculation of fringing factor is very important for accurate estimation of the resonant frequency of the antenna. This is crucial, because the effective dimension of the antenna and the effective dielectric constant directly affect the resonant frequency. Thus, based on the following [12], [27], [28], an equivalent circular patch with radius  $a_c$  has been consider, resonating at the same zero order frequency as does the sector patch antenna with radial dimension  $a$ . This helps to establish a relationship amongst the dimensions of both the geometries in a simplified way. Equating the zero order resonant frequencies [4], [24] of both the patches and it can be represents as

$$f_{0,r} = \frac{\chi'_{11}c}{2\pi a_c \sqrt{\epsilon_r}} = \frac{\chi'_{mn}c}{2\pi a \sqrt{\epsilon_r}} \quad (2.26)$$

$$a_c = \frac{\chi'_{11}}{\chi'_{mn}} a = \frac{1.84a}{\chi'_{mn}} \quad (2.27)$$

$\chi'_{mn} = 1.84$  when  $\phi_0 = 180^\circ$ , as suggested in section 2.2.1, Case-I (semicircular patch),

$\chi'_{mn} = 3.05$  when  $\phi_0 = 90^\circ$ , as suggested in section 2.2.1, Case-II ( $90^\circ$  circular sector patch),

$\chi'_{mn} = 3.83$  when  $\phi_0 = 60^\circ$ , as suggested in section 2.2.1, Case-III ( $60^\circ$  circular sector patch).

Thus, the fringing factor  $q_l$  can be calculated from the circular patch [28], equivalent to the CSMA, as done in [13] for a RMA. Therefore, equation (2.26) has been established to correlate with the sector patch with circular patch. It may be noted that ( $q_l$ ), in case of circular sector patch, is determined from the corresponding fringing factor of the circular patch [28]. This fringing factor ( $q_l$ ) is utilized in equation (2.25) to obtain the effective dimension ( $a_{eff}$ ) of circular sector patch.

### 2.2.3 Calculation of Effective Dielectric Constant

An effective dielectric constant can be calculated, based on static and dynamic capacitances [20]-[21]. When an air gap of height  $h_2$  is introduced between the substrate (thickness  $h_1$ , dielectric constant  $\epsilon_r$ ) and the ground plane as shown in Fig. 2.1, the equivalent dielectric constant of the medium below the patch becomes

$$\epsilon_{re} = \frac{\epsilon_r (1 + h_2/h_1)}{(1 + \epsilon_r h_2/h_1)} \quad (2.28)$$

The dynamic dielectric constant  $\epsilon_{rdyn}$  is given by

$$\epsilon_{rdyn} = \frac{C_{dyn}(\epsilon = \epsilon_0 \epsilon_{re})}{C_{dyn}(\epsilon = \epsilon_0)} \quad (2.29)$$

where,  $C_{dyn}$  is the total dynamic capacitance [20], which can be expressed as

$$C_{dyn} = C_{0,dyn} + C_{e,dyn} \quad (2.30)$$

Here,  $C_{0,dyn}$  is the dynamic capacitance for the fields stored under the disc i.e. the case with no fringing and  $C_{e,dyn}$  is the dynamic fringing capacitance that arises from fringing effect.

Now following [20],  $C_{0,dyn}$  can be written as

$$C_{0,dyn} = \frac{\varepsilon_0 \varepsilon_r \pi a_c^2}{\delta h} \left[ 1 - \frac{J_{m-1}(\chi'_{mn}) J_{m+1}(\chi'_{mn})}{J_m^2(\chi'_{mn})} \right] \quad (2.31)$$

$$= \gamma_m C_{0,stat}$$

where,

$$\delta = 1 \text{ for } m=0 \text{ and } \delta = 2 \text{ for } m \neq 0. C_{0,stat} = \frac{\varepsilon_0 \varepsilon_r \pi a_c^2}{\delta h} \quad (2.32)$$

and

$$\gamma_m = \left[ 1 - \frac{J_{m-1}(\chi'_{mn}) J_{m+1}(\chi'_{mn})}{J_m^2(\chi'_{mn})} \right] \quad (2.33)$$

Here,  $\gamma_m$  is the factor by which the dynamic capacitance for the fields stored under the disc can be computed and it is strictly depends on mode number  $m$ .

Therefore, using the equations (2.21)-(2.24), equation (2.20) may be expressed as

$$\varepsilon_{rdyn} = \frac{\varepsilon_{re} \left[ \gamma_m + \frac{q_1}{2} \right]}{\left[ \gamma_m + \frac{q_{01}}{2} \right]} \text{ (for } m \neq 0) \quad (2.34)$$

$$\varepsilon_{rdyn} = \frac{\varepsilon_{re} [\gamma_m + q_1]}{[\gamma_m + q_{01}]} \text{ (for } m = 0) \quad (2.35)$$

$$\gamma_m = 1.0 \text{ for } m = 0$$

$$= 0.3525 \text{ for } m = 1$$

$$= 0.2865 \text{ for } m = 2$$

$$= 0.2450 \text{ for } m = 3$$

and,  $q_{01}$  is the fringing factor when  $\varepsilon_r=1$ .

Thus, the effective dielectric constant  $\varepsilon_{reff}$  becomes, as in [19],

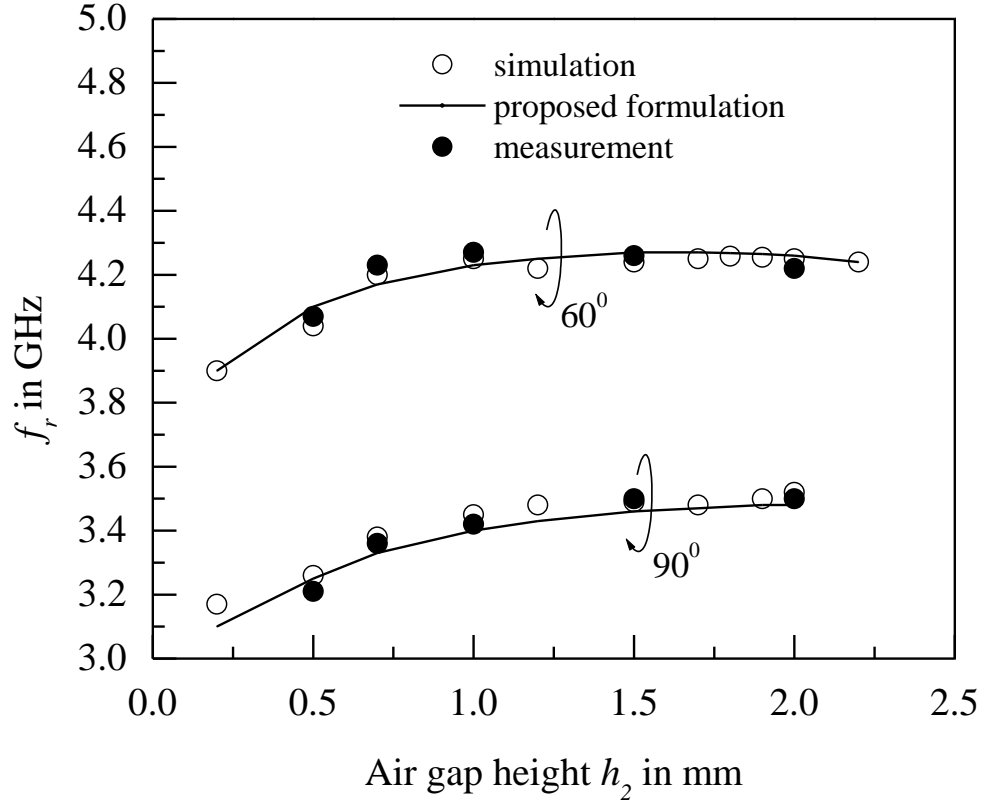

$$\varepsilon_{re\text{ff}} = \frac{4\varepsilon_{re}\varepsilon_{rdyn}}{\left(\sqrt{\varepsilon_{re}} + \sqrt{\varepsilon_{rdyn}}\right)^2} \quad (2.36)$$

### 2.3 Results and Discussions

In this section, the data obtained by using the proposed formulation is compared with the data obtained by simulation, measurement and other available theories or formulations in literature. The experiments have carried out with different prototypes and the results obtained are presented here to validate the present formulation.

In Fig. 2.5, the calculated resonant frequencies of S band CSMA for different air gap heights are compared with the simulation results [22] and some own measurement. Fig. 2.5 shows that the average percentage (%) deviations of simulation and theoretical results, with respect to the measurement results, are around 0.40% and 0.65% respectively, for  $60^\circ$  sector. The corresponding deviations for  $90^\circ$  sector are 0.59% and 0.81%, respectively. There is a good agreement amongst simulation, theoretical and measurement results for both the sector angles.

The tunability of the CSMA, as a function of the air gap height, is also revealed to be the same as what is expected from the patch antennas with conventional geometry. In fact, the introduction of air gap between the substrate and the ground plane effectively increases the air content between the patch and the ground plane. This, in turn, reduces the effective dielectric constant of the substrate which increases the resonant frequency of a antenna structure. The proposed formulation is compared with some previously published formulations [3]-[5] in Table 2.1. The proposed formulation is found to offer minimum average percent error of 0.95%, in comparison to simulation.

**Fig. 2.5** Variation of resonant frequency of CSMA (for two sector angles) as a function of air gap height  $h_2$  with  $a = 30$  mm,  $h_1 = 1.575$  mm,  $\epsilon_r = 2.33$ .

Some measured results are also incorporated in this table for further validation of the proposed formulation. The data presented in Table 2.1 reveals a close agreement between the proposed formulation and the measurement results.

It further reveals that, in comparison with the measurement results, the proposed formulation offers only around 0.75% error in estimating the resonant frequencies of CSMA, while the errors reported in [3]-[4] are around 3.95%. Therefore, from an examination of the data presented in Table 2.1, it follows that the proposed formulation offers minimum % error with respect to both simulation [22] and measurement results, as also the results of earlier theories. The validity of modified formulation in the case of CSMA with substrates of different electrical thicknesses has been verified. In Fig. 2.6 the verification reveals an excellent agreement between simulated, theoretically computed results and measured results for two different sector angles. However, there is a visible deviation in predicted resonant frequency in the figure when  $h_1 = 4$  mm, in comparison to full wave simulation.

**TABLE 2.1** Comparison of the computed [proposed formulation] resonant frequencies of CSMA for different sector angle with that of earlier theories and simulation;  $h_2=0$ ,  $h_l=1.575$  mm.

In general, when the thickness of the substrate exceeds about 2% of the free space wavelength, the cavity model starts giving inaccurate results, because of the breakdown of the basic assumptions of the cavity model, as indicated clearly in [25].

Moreover, a simple cavity model does not account for the fringing effect along the periphery of the patch. Therefore, in the proposed formulation, the fringing fields along the periphery of the patch have taken care by appropriately modeling the cavity boundary.

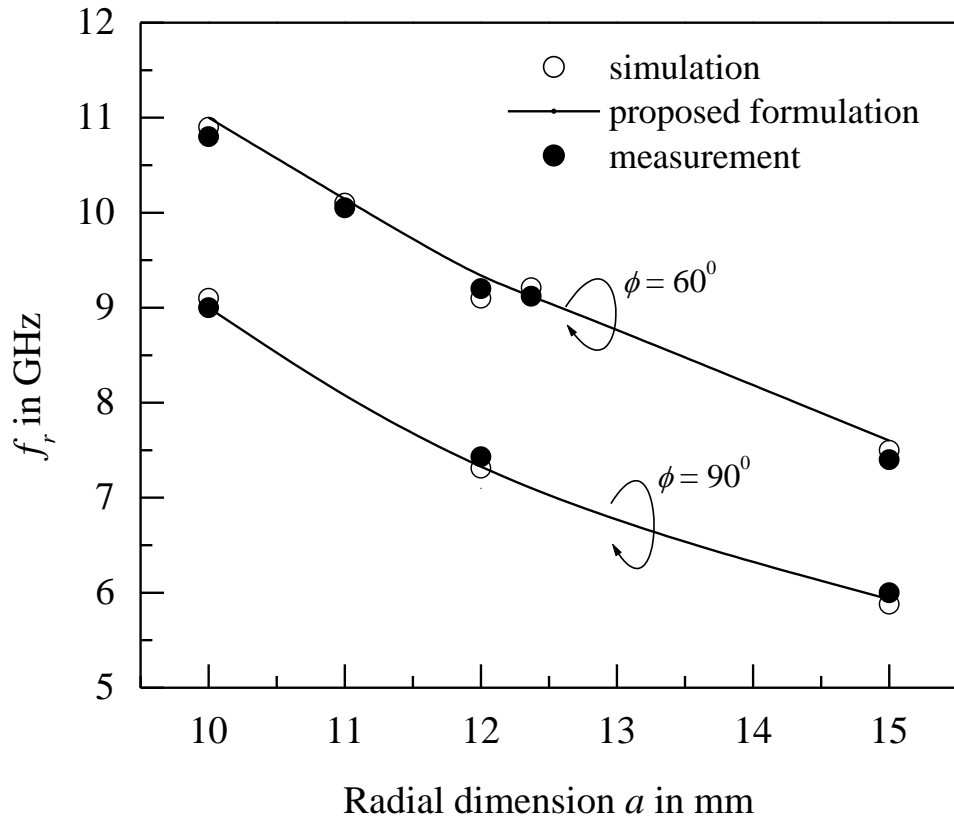

**Fig. 2.6** Variation of resonant frequency of CSMA (for two sector angles) as a function of substrate thickness  $h_1$  with  $a = 30$  mm,  $h_2 = 0$ ,  $\epsilon_r = 2.33$ .

**Fig. 2.7** Variation of resonant frequency of CSMA (for two sector angles) as a function of dielectric constant of the substrate with  $a = 30$  mm,  $h_1 = 1.58$  mm,  $h_2 = 0$ .

However, when the thickness becomes too large, i.e., when it exceeds 4.0% of free space wavelength; the results show around 1.7-2.0% deviation of resonant frequency in comparison to that of full wave simulation. However, this much of deviation in the prediction of resonant frequency is acceptable for a microstrip patch etched over a thick substrate. Unfortunately, reports dealing with resonant frequencies of CSMA over thick substrates are rather scarce. The resonant frequencies of CSMA with widely varying substrate permittivity ( $\epsilon_r$  varying from 2.2 to 10.2) are shown in Fig. 2.7.

The values computed from the proposed formulation are compared with the results obtained from [22] and from measurement. Excellent agreement between the present theory and simulation [22] and measured results are revealed. Superiority of the proposed formulation in addressing the resonant frequency of CSMA with different radial dimensions for two different sector angles has been examined through Fig. 2.8.

**Fig. 2.8** Variation of resonant frequency of CSMA (for two sector angles  $\phi = 60^\circ$  and  $90^\circ$ ) as a function of radial dimension  $a$  of the antenna with  $h_1 = 0.787$  mm,  $h_2 = 0$ ,  $\epsilon_r = 2.2$ .

Some of the own measurement results are also incorporated in the same plot in support of the proposed formulation and to unravel the close agreement between the theoretical, simulation and measurement results. For further corroboration of the proposed formulation, some simulated and results are presented in Table 2.2 & Table 2.3 for  $\varphi = 60^0$ ,  $30^0$  and  $45^0$ .

**TABLE 2.2** Comparison of the simulated, and computed [proposed formulation] resonant frequencies of CSMA for  $60^0$  sector angle with air gap;  $\epsilon_r = 2.2$ ,  $h_2 = \text{variable}$ .

The ability of the proposed formulation in addressing and identifying the higher order modes for different sector angles, with and without air gap, is also investigated and the results are presented in Table 2.4. The investigation has been performed on CSMA's having different dielectric constants. Comparison of the proposed formulation results with those of the simulation in each case reveals excellent conformity between the two.

All the simulation results of the investigation have been obtained by keeping the feed location at the matched position for the dominant mode. As such, the  $S_{11}$  minima corresponding to all the higher modes, have had no sufficient dip, as a result of which, it might have lost the order of accuracy in indicating simulated resonant frequency. That explains why, in a few cases presented in Table 2.4, the simulation results show a slight deviation with respect to the values computed, using the proposed formulation.

**TABLE 2.4** Comparison of the simulated and computed [proposed formulation] resonant frequencies of higher order modes for CSMA for different sector angles and different substrate permittivity.

|                         |               |             |              |               | $TM_{41}$              | 5.10                             | 4.97  |
|                         |               |             |              |               | $TM_{02}$              | 6.15                             | 6.40  |

By solving the field equations and observing the roots of the derivative of the Bessel function ( $\chi'_{mn}$ ) in order, the higher order modes are theoretically evaluated. For visualization-based understanding of the dominant and higher order modal fields, the magnitudes of electric fields over the patch surface, for a few higher modes, have been presented in Fig. 2.9 for a few higher order modes listed in Table 2.4.

(a)

(b)

**Fig. 2.9** Electric Field magnitude over the patch surface of CSMA (with  $60^\circ$  sector angle) for higher order modes (a)  $TM_{31}$  mode ( $f = 4.14$  GHz), (b)  $TM_{61}$  mode ( $f = 7.23$  GHz), (c)  $TM_{62}$  mode ( $f = 11.0$  GHz), Parameters:  $a = 30$  mm,  $h_1 = 1.575$  mm,  $h_2 = 0$ ,  $\epsilon_r = 2.33$ .

Following [26], the higher order modes of CSMA, for  $\varphi = 60^\circ$ , have been identified. According to the discussions presented in section 2.2.1, the number of variations in electric field along the radial direction (along  $\rho$  direction) is  $n$  and that along the circumferential direction (along  $\varphi$  direction) is  $q$  ( $m = 3q$ ; for  $\varphi = 60^\circ$ ). Therefore, by inspecting the number of electric field variations along  $\rho$  and  $\varphi$  variations the mode  $TM_{mn}$  can be identified.

In Fig. 2.9 (a), one radial variation ( $n=1$ ) and one circumferential variation ( $q = 1$ ;  $m = 3$ ) are evident, as expected for  $TM_{31}$  mode. Similarly, two circumferential variations ( $q = 2$ ;  $m = 6$ ) and one radial variation ( $n = 1$ ) corresponding to  $TM_{61}$  mode, and two circumferential variations ( $q = 2$ ;  $m = 6$ ) and two radial variations ( $n = 2$ ) corresponding to  $TM_{62}$  mode are manifested in Fig. 2.9 (b) and 2.9 (c), respectively. Compared to Fig. 2.9, Fig. 2.3 shows one variation ( $n = 1$ ) in electric field along the radial direction, corresponding to  $TM_{01}$  mode, but no variation along the circumference ( $q = 0$ ;  $m = 0$ ). This observation is remarkably in tune with what has been discussed in the theoretical part (section 2.2.1, Case-III). Besides, it further

corroborates the superiority of the proposed formulation in predicting the dominant and higher order modes for sector patch antennas, with and without air gap.

| % of relative error with respect to measurement |             |               |              |      |  | -  | 0.32%  |

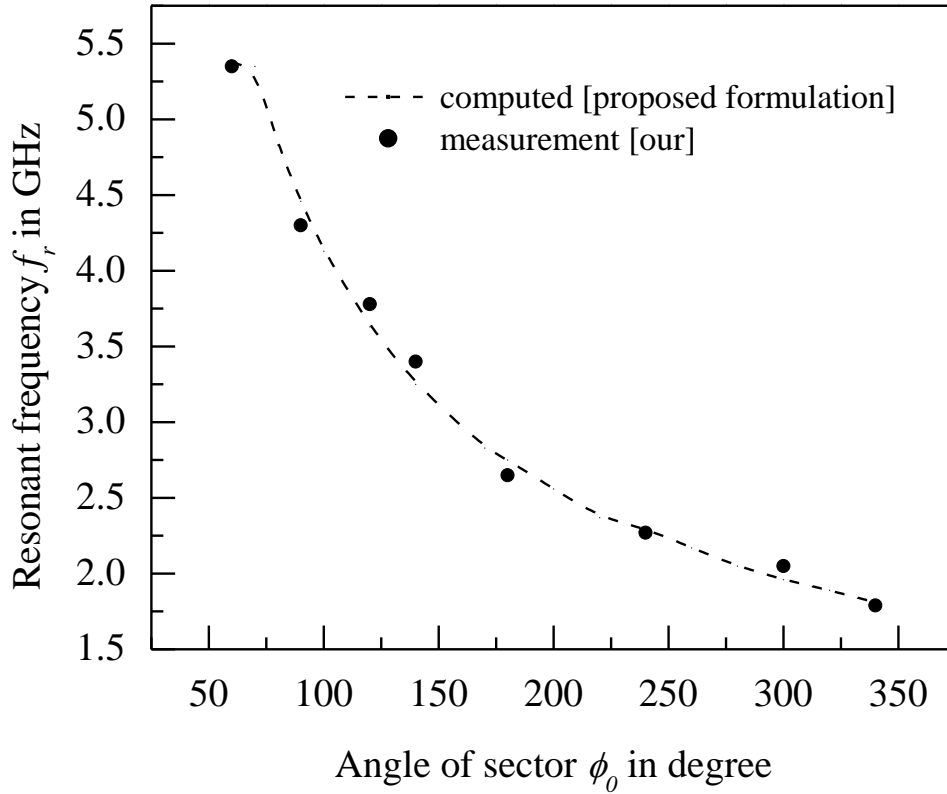

The reliability of the proposed formulation is thus established for designing the CSMA, with and without air gaps. For further confirmation, the predicted results, based on the proposed formulation, have been compared with the simulated and our own measured results.

**TABLE 2.6** Comparison of the measured and computed [proposed formulation] resonant frequencies of dominant modes of CSMA for different sector angles and substrate thicknesses  $h_l \sim 3$  mm.

| Sector angle<br>$\varphi_0$<br>(degree) | $a$<br>(mm) | $\epsilon_r$ | Measured $f_r$<br>(MHz)<br>[11], [24] ** | Computed $f_r$ in MHz<br>[proposed formulation] |
|---|-------------|--------------|--|---|
| 340 <sup>0</sup>                        | 70          | 1            | 778                                      | 780   |
| ** 120 <sup>0</sup>                     | 21.9        | 2.55         | 3181                                     | 3183  |

Measured data from some earlier reports has also been included in the comparative study to verify the validity of the proposed formulation (Tables 2.5 and Tables 2.6).

The comparative study reveals an excellent agreement amongst the measured, simulated and theoretically computed results. The theoretical and measurement results for dominant mode resonant frequencies of CSMA (printed on widely available polytetrafluorethylene (PTFE) substrate;  $\epsilon_r = 2.33$ ,  $h_1 = 1.59$  mm) for wide variety of sector angles are presented in Fig. 2.10.

**Fig. 2.10** Comparison of computed and measured dominant mode resonant frequency of CSMA with different sector angles ( $\phi_0$ ). Parameters:  $a = 20$  mm,  $h_1 = 1.58$  mm,  $h_2 = 0$ ,  $\epsilon_r = 2.33$ .

It may be noted that, the present approach may be extended to compute the dominant mode frequency of circular patch.

In fact, the CSMA with  $\phi = 2\pi$  degree degenerates to conventional circular patch where, the radial component of magnetic fields ( $H_\rho$ ) at  $\phi = 0^\circ$  and  $\phi = 2\pi$  are continuous with the boundary condition of continuity of tangential component of magnetic fields. Following the same, the lowest order mode of CSMA with  $\phi = 2\pi$  degree (circular patch) becomes  $TM_{11}$ . The present investigation ought to be very

much useful to the scientific community for quick and accurate calculations of lowest order resonant frequency of CSMA of any sector angle.

## 2.4. Conclusion

CSMA with and without air gap has been thoroughly studied. An improved CAD formulation is proposed for accurate prediction of its resonant frequency. The proposed formulation is validated thoroughly for CSMA with widely varying antenna parameters by several measurement and simulation data. The proposed formulation can efficiently compute the dominant mode along with the higher order modes of CSMA with any sector angle. The proposed CAD formulation appears to be much improved, versatile and simple compared to the earlier reported theories. However, the effect of feed location on the modes and its frequency is a critical issue which will be addressed thoroughly in a separate investigation.

## **Insightful Exploration of Feed Dependent Modes of Circular Sector Microstrip Antenna**

### **3.1. Introduction**

In the recent years, there is a growing inclination on exploring and enhancing the radiation and input characteristics of circular sector microstrip antenna (CSMA) for modern applications due to its conformality over curved surfaces, and better compactness in comparison with other regular shaped patch geometries such as rectangular, circular as is discussed in Chapter 1. This circular sector microstrip antenna with and without variable air-gap height, has been documented in Chapter 2. The accurate determination of lowest order dominant and its frequency along with determination of higher mode has been methodically discussed in previous chapter. Apart from that, the accurate estimation of the feed-probe position for the excitation of desired modes in a CSMA is another basic design requirement.

In the recent years, significant works [1]-[4] has been reported on CSMA for yielding circular polarization well as multibanding. Notably, all these reported works, the measurement has been instigated on based on appropriate simulation to optimize the proposed CSMA structure. The possibility of using fractional modes in CSMA has been demonstrated in few literatures [5]-[6], to excite multiple higher order modes simultaneously. This has been done by optimizing sector angle of the CSMA, which yields dual resonances or broadband characteristics without focusing the feed location dependency on the excited mode. The feed locations were elected along the middle line of the sector (bi sector line) to ease the feeding of a CSMA structure and hence could not excite the lowest order mode. Also, to achieve

desirable characteristic of CSMA, feed locations have been elected intuitively. Notably, in [7]-[11] the CSMA has been investigated to determine its resonant frequency. The effects of feed point for excitation of different modes have been rigorously analyzed for Circular microstrip antenna (CMA) [12]. It is observed that the excitation of dominant mode  $TM_{11}$  is always strong when it is feeding centrally or near to the centre of the patch. When the patch was fed near the edges the higher order  $TM_{21}$  mode has a tendency to be excited. Nevertheless, the peak excitation of that  $TM_{21}$  mode was always below 24 dB than the  $TM_{11}$  mode. In case of rectangular microstrip antenna two orthogonal resonance ( $TM_{10}$  and  $TM_{01}$ ) modes can be simultaneously excited by feeding it from two sides [13]. Similarly, the feed-probe position of a CSMA also has a substantial effect on the excitation of a desired mode. Consequently, the serious attention and thorough methodical investigations are required to correctly understand the modal behavior of the CSMA as a function of feed position. In this context no such open-literatures are available till date. Therefore, the simple, quick hand, but accurate technique must have been explored to excite its proper mode and to understand the influence of feed positions on modal characteristics of a CSMA for a number of sector angles ( $\phi_0$ ). From the view of less space requirement, CSMA with sector angle ( $\phi_0$ ) less than  $180^\circ$  have been considered here in Fig. 3.1.

Unlike earlier investigations, in which researchers used the trial-and-error approach to design a CSMA for particular applications based on simulations, here, the investigations on modal properties as a function of feed location has been carried out methodically and an quick hand empirical but accurate technique has been proposed to estimate the feed location to excite a particular mode in CSMA.

Unlike CMA, the impedance variations of a CSMA when tuning the feed position do not happen only along the radial distance but also along the azimuth angle. Till date, no accurate impedance formulation for a CSMA is available. Hence, the  $E/H$  ratio has been exploited to find a proper feed location for exciting a particular mode.

The determination of modes of a CSMA based on feed location investigated in this work is not reported elsewhere.

### 3.2 Theoretical Insight

A CSMA resonates at its lowest order primary dominant mode which depends critically on both the radial dimension of the patch and sector angle. The field distributions within the substrate can be written as [11]

$$\left. \begin{aligned} \bar{E}_z &= B_{mnp} A \cos(m\phi) J_m(k_\rho \rho) \cos(k_z z) \\ \bar{H}_\rho &= \frac{-j}{\omega \mu \rho} B_{mnp} J_m(k_\rho \rho) (mA \sin m\phi) \cos(k_z z) = \frac{1}{\omega \mu \rho} B_{mnp} J_m(k_\rho \rho) (mA \sin m\phi) \cos(k_z z) e^{-j\frac{\pi}{2}} \\ \bar{H}_\phi &= -j \frac{k_\rho}{\omega \mu} B_{mnp} A \cos(m\phi) J'_m(k_\rho \rho) \cos(k_z z) = \frac{k_\rho}{\omega \mu} B_{mnp} A \cos(m\phi) J'_m(k_\rho \rho) \cos(k_z z) e^{-j\frac{\pi}{2}} \end{aligned} \right\} (3.1)$$

Where,  $k_\rho = \chi'_{mn}/a$ ;  $a$  = radial dimension of a CSMA, and  $\chi'_{mn}$  is constant. Here,  $\rho$  is defined as radial dimension from the apex of the patch to the edge of patch such that  $0 < \rho \leq a$ , where  $a$  is the maximum radial dimension of the patch.  $k_\rho$  is the propagation constant along the radial dimension ( $\rho$ ) and  $k_z$  is the propagation constant along the  $z$  direction.  $J_m$  and  $J'_m$  are the Bessel function and derivative of Bessel function of order  $m$  in relation to  $(k_\rho \rho)$ , respectively.  $\mu$  refers to the permeability of the medium, and  $\omega$  is the angular frequency.  $A$  and  $B_{mnp}$  are constants,  $m$  is ((number of circumferential variation  $\times \pi$ )/ $\phi_0$ ) and  $n$  is the root of derivative of Bessel function of order  $m$  in relation to  $(k_\rho \rho)$ . In equation (3.1),  $\bar{H}_\rho$  and  $\bar{H}_\phi$  are radial and circumferential components of magnetic field  $\bar{H}$ . Therefore, at a particular point, the magnitude of magnetic field is

$$|\bar{H}| = \frac{1}{\omega \mu} B_{mnp} A \left[ \frac{m^2}{\rho^2} J_m^2(k_\rho \rho) \sin^2(m\phi) + k_\rho^2 J'_m{}^2(k_\rho \rho) \cos^2(m\phi) \right]^{1/2} \quad (3.2)$$

and the phase is  $-\pi/2$ .

$$\text{Hence, } \frac{\bar{E}_z}{\omega\mu\bar{H}} = \frac{\cos(m\phi)J_m(k_\rho\rho)}{\left[\frac{m^2}{\rho^2}J_m^2(k_\rho\rho)\sin^2(m\phi) + k_\rho^2J_m'^2(k_\rho\rho)\cos^2(m\phi)\right]^{1/2}} e^{j\frac{\pi}{2}} \quad (3.3)$$

Therefore, the magnitude of equation (3.3) can be written as,

$$\left|\frac{\bar{E}_z}{\omega\mu\bar{H}}\right| = \frac{|\cos(m\phi)J_m(k_\rho\rho)|}{\left[\frac{m^2}{\rho^2}J_m^2(k_\rho\rho)\sin^2(m\phi) + k_\rho^2J_m'^2(k_\rho\rho)\cos^2(m\phi)\right]^{1/2}} \quad (3.4)$$

and the phase of equation (3.4) is  $\pi/2$ , as is expected from a parallel resonating circuit. This is customary as the basic microstrip antennas are modeled with parallel resonating circuits. Notably, this phase shift of  $\pi/2$  in between the electric and magnetic field is constant, and it is not the function of the CSMA parameters. In [13], the input impedance of a circular patch has been thoroughly analyzed by modeling the feed probe (using the current ribbon model), and it has exhibited similar and constant phase difference of  $\pi/2$  between the input voltage  $V$  and current  $I$ , which is in agreement with our concept. Therefore, to avoid further complexity, the phase shift between  $E$  and  $H$  is not considered in the further analysis.

This electric to magnetic field ratio ( $E/H$  ratio) beneath the patch is noteworthy to understand the impedance behavior, as well as to excite a particular mode in a CSMA with specific sector angle. The input impedance of the CSMA at a particular feeding position must depend on this  $E/H$  ratio at that point. In a more compact form, equation (3.4) is denoted as

$$\left|\frac{\bar{E}_z}{\omega\mu\bar{H}}\right|^{-2} = \left(\frac{m^2}{\rho^2}\right)\tan^2(m\phi) + k_\rho^2\frac{J_m'^2(k_\rho\rho)}{J_m^2(k_\rho\rho)} \quad (3.5)$$

The resonant frequency of a CSMA can be obtained from [11] using modified cavity model (with boundary of PEC walls at top and bottom and PMC walls along sector edges where  $H_\rho=0$  at  $\phi=0^\circ$  and  $\phi=\phi_0$  and  $H_\phi=0$  at  $\rho=a$  for  $\phi=0^\circ$  to  $\phi_0$ ) as

$$f_r = \frac{\chi'_{mn}c}{2\pi a_{eff}\sqrt{\epsilon_{reff}}} \quad (3.6)$$

Where,  $\chi'_{mn}$  is the  $n^{th}$  root of derivative of Bessel function of order  $m$  in relation to  $(k_\rho \rho)$ ,  $a_{eff}$  is the effective dimension of the antenna with fringing, and  $\epsilon_{reff}$  is the effective dielectric constant which includes the static and dynamic capacitance of patch. These capacitances are the function of physical dimensions i.e radial dimension  $a$ , sector angle  $\phi_0$ , and the substrate thickness  $h$ . Therefore, the above parameters will affect the mode and it's frequency.

The effective power ( $P_{excited}$ ) delivered by the feed-probe to the patch corresponding to a particular mode is

$$P_{excited} = \int \bar{E} \bullet \bar{J} dv \quad (3.7)$$

Where  $\bar{J}$  is the excitation of feed-probe current density and  $\bar{E}$  is the induced electric field. Therefore, to excite the specific mode in the CSMA, the coaxial feeding probe (current source) must be placed at the position that has sufficient electric field.

### 3.3 Modal Characteristics of a CSMA

The CSMA with different range of sector angles with different characteristics as a function of feed location has been investigated thoroughly. Based on thorough and methodical investigation with different sector angles have been categorized and discussed in the following section.

#### 3.3.1 CSMA with Sector Angle $0^\circ < \phi_0 \leq 60^\circ$

The dominant mode of a CSMA with sector angle  $0^\circ < \phi_0 \leq 60^\circ$  is  $TM_{01}$  ( $m = 0$  and  $n = 1$ ) [11]. When  $m = 0$ , the  $E/H$  ratio is independent of azimuthal angle  $\phi$  and it solely depends on the Bessel function of order  $m$  and argument  $(k_\rho \rho)$ , as seen in Eq. (3.5). Therefore, it varies along the radial direction and there is no variation along the circumferential direction  $\phi$ . The computed (based on Eq.3.5) variation of  $(E/\omega\mu H)$  ratio as a function of radial dimension is shown in Fig. 3.2 (a) at  $\phi = 0^\circ$  and  $\phi_0/2$  for  $45^\circ$  CSMA at dominant  $TM_{01}$  mode. It is found that the variation is identical for both the cases with feeding along the  $\phi_f = \phi = 0^\circ$  line or along the  $\phi_f = \phi = \phi_0/2$  line. Therefore, whether the CSMA is fed along central symmetrical position ( $\phi_f = \phi = \phi_0/2$  line) or along the edge ( $\phi_f = \phi = 0^\circ$  line); the feed-probe would experience similar type of impedance variation, and hence only  $TM_{01}$  mode is excited in the

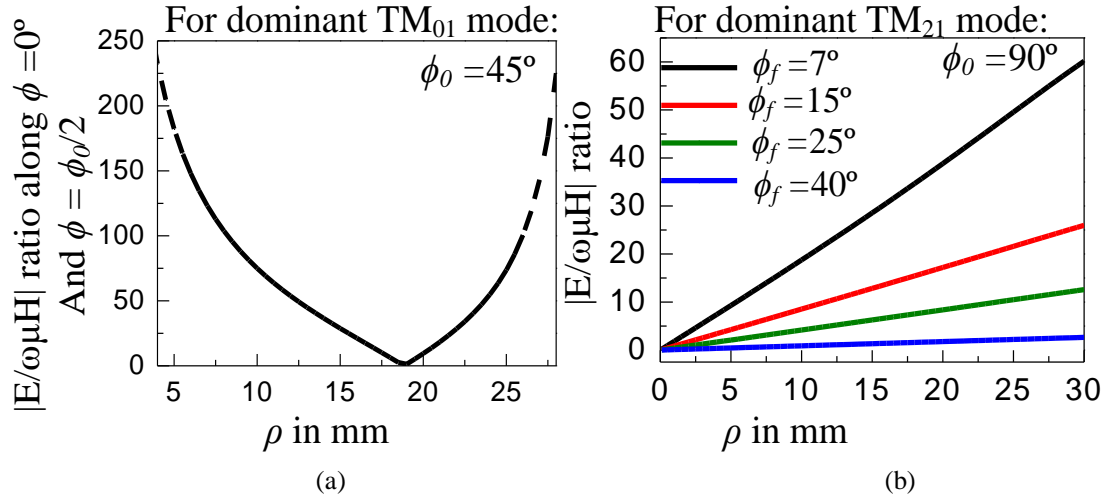

CSMA. Thorough investigations via [14] with all sector angles up to  $60^\circ$  shows that the dominant  $TM_{01}$  mode can always be excited in the CSMA and it is independent of azimuthal feed-probe location  $\phi_f$ . Furthermore, the resonant frequency of the CSMA with  $0^\circ < \phi_0 \leq 60^\circ$  is fully dependent on the radial dimension ( $\rho$ ) of the patch and not on the sector angle  $\phi_0$ . The fields beneath the patch for the mode with  $m = 0$  resonates along the  $x$ - $x'$  direction, its E and H planes are corresponding to  $x$ - $z$  and  $y$ - $z$  respectively. Consequently, the radiated electric field for such CSMA is  $x$  polarized.

### 3.3.2 CSMA with Sector Angle $60^\circ < \phi_0 \leq 170^\circ$

In case of CSMA with sector angles  $60^\circ < \phi_0 \leq 170^\circ$ , the dominant modes have  $m \neq 0$ . It is realized from Eq. (3.5) that when  $m \neq 0$ , the  $E/H$  ratio depends on both the azimuth angle  $\phi$  and the Bessel function of order  $m$  and argument ( $k_\rho \rho$ ). Therefore, the impedance variation for the mode with  $m \neq 0$  within the CSMA is of complex nature and it varies along the radial direction  $\rho$ , as well as the circumferential direction  $\phi$ . Furthermore, when the antenna is fed along the central symmetrical  $\phi = \phi_0/2$  line, it would encounter different impedance variation compared to the one that fed along the  $\phi = 0^\circ$  line as this  $E/H$  ratio is closely related to  $V/I$  ratio, i.e., the impedance at the feed-probe location.

Thorough investigations via [14] shows that for the CSMA with sector angles  $60^\circ < \phi_0 \leq 110^\circ$ , the dominant modes of the CSMA are fractional modes and can only be excited when the CSMA is fed along the edge i.e. along  $\phi = 0^\circ$  line. When the patches are fed along the central symmetrical  $\phi = \phi_0/2$  line; the excited modes are the next higher order  $TM_{01}$  mode. Hence, to excite the proper lowest order dominant mode, the CSMA should be fed along the edge i.e.  $\phi_f = \phi = 0^\circ$  line. The variation of  $(E/\omega\mu H)$  ratio as a function of radial dimension ( $\rho$ ) for  $90^\circ$  CSMA at its dominant  $TM_{21}$  mode is shown in Fig.3.2(b) for different azimuth angle of feeding values ( $\phi_f$ ) i.e. from edge ( $\phi_f = 7^\circ$ ) to  $\phi_f \approx \phi_0/2$ . Notably, the slope of  $(E/\omega\mu H)$  ratio as a function of  $\rho$  is not the same for different feeding angle  $\phi_f$ . The maximum value of the ratio is obtained at the edge i.e at  $\rho = a$  for all  $\phi_f$  values. However, these maximas are different for different  $\phi_f$ . This indicates that, for different  $\phi_f$ , one needs to optimize the feed position as a function of  $\rho$ . It is also noted from Fig. 3.2. (b) that the  $E/H$

ratio exhibits its higher value near the edge of the CSMA, i.e., along  $\phi_f = 7^\circ$ , as compared to other  $\phi_f$  values, and there is not much variation of  $E/H$  ratio beyond  $\phi = 25^\circ$  in the case of  $90^\circ$  CSMA, as there is null electric field at the central region of the patch (that is  $\phi_0/2$ ) for  $TM_{21}$  mode. Therefore, optimizing the feed location as a function of  $\rho$  becomes useless to excite the dominant  $TM_{21}$  mode in  $90^\circ$  CSMA if it is fed along the central  $\phi_f = \phi_0/2$  line. Interestingly, if the feed probe is placed along the  $\phi_f = \phi_0/2$  line, the next higher order mode  $TM_{01}$  can easily be excited in the  $90^\circ$  CSMA. This behavior of CSMA is valid for all the sector angles with  $60^\circ < \phi_0 \leq 110^\circ$ .

**Fig. 3.2** Variation of  $(E/\omega\mu H)$  ratio as a function of radial dimension for CSMA with (a)  $\phi_0 = 45^\circ$  and (b)  $\phi_0 = 90^\circ$ . (CSMA parameters: radius  $a = 30$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.)

Therefore, for all such centrally fed ( $\phi_f = \phi_0/2$ ) CSMAs ( $60^\circ < \phi_0 \leq 110^\circ$ ), the excited mode is the same i.e.  $TM_{01}$  and consequently its frequency is solely dependent on the radial dimension of the patches and is independent of the sector angle of the CSMA. Nevertheless, if those CSMAs are fed along the edge (near  $\phi = 0^\circ$  line), the proper dominant mode (e.g.  $TM_{2.25\ 1}$  for  $80^\circ$ ,  $TM_{21}$  for  $90^\circ$ ,  $TM_{1.63\ 1}$  for  $110^\circ$  and so on) can be excited. In those cases, the fields beneath the patches for the mode with either  $m = 2.25$  or  $2$  or  $1.63$ ; the number of circumferential variation  $q = 1$  and resonates along the  $y$ - $y'$  direction and hence its E and H planes are corresponding to  $y$ - $z$  and  $x$ - $z$ , respectively. Consequently, the radiated electric field for such cases is  $y$  polarized. On the contrary, if the same patches ( $60^\circ < \phi_0 \leq 110^\circ$ ) are fed along the central symmetrical  $\phi = \phi_f = \phi_0/2$  line, the fields beneath the patches for  $TM_{01}$  mode

resonates along the  $x$ - $x'$  direction and the radiated electric field for such cases is  $x$  polarized. The simulated reflection coefficient profiles for  $90^\circ$  CSMA fed at different  $\phi_f$  are shown in Fig. 3.3. Here, the excitation of higher order  $TM_{0l}$  mode is exhibited, instead of the dominant  $TM_{2l}$  mode beyond  $\phi_f = 25^\circ$ . Similar to the previous cases, the dominant modes of the CSMA ( $110^\circ < \phi_0 \leq 170^\circ$ ) can also be excited when the patch is fed along the edge i.e., along  $\phi = 0^\circ$  line.

**Fig. 3.3** Simulated  $S_{11}$  profile for a CSMA with  $\phi_0 = 90^\circ$  fed along different azimuthal feed locations  $\phi_f$ . (CSMA parameters: radius  $a = 30$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.)

Once the CSMA of such angles are fed along the central symmetrical  $\phi = \phi_f = \phi_0/2$  line; they will exhibit the next higher order modes ( $TM_{2mn}$ ) that are not the same for different sector angles  $\phi_0$  and they are not similar to  $TM_{0l}$  mode (independent of  $\phi_0$  as was the above case for CSMA with  $60^\circ < \phi_0 \leq 110^\circ$ ).

Consequently, the CSMA with  $110^\circ < \phi_0 \leq 170^\circ$  exhibit their proper dominant modes (e.g  $TM_{1.5\ 1}$  for  $120^\circ$ ,  $TM_{1.2\ 1}$  for  $150^\circ$ ,  $TM_{1.05\ 1}$  for  $170^\circ$  and so on) when they are fed along the  $\phi_f = \phi = 0^\circ$  line, and in that case, the fields beneath the patches resonates along the  $y$ - $y'$  direction and hence, the radiated electric field for such cases is  $y$  polarized. On the contrary, the centrally fed CSMA ( $\phi_f = \phi_0/2$  line) with such sector angles exhibit the next higher order  $TM_{2mn}$  modes (e.g  $TM_{3\ 1}$  for  $120^\circ$ ,  $TM_{2.4\ 1}$

for  $150^\circ$ ,  $TM_{2,1,1}$  for  $170^\circ$  and so on). The variation of  $(E/\omega\mu H)$  ratio for  $120^\circ$  CSMA as a function of radial dimension ( $\rho$ ) and azimuth angle at its dominant mode have exhibited similar profiles as in Fig. 3.2 (b). The simulated electric field distributions of the patch for three group of sector angles are presented in Fig. 3.4.

(a)

(b)

(c)

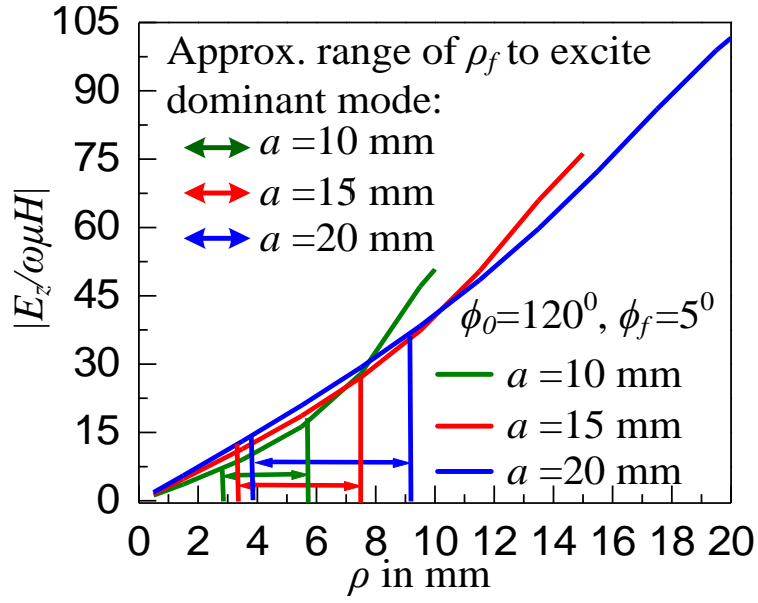

**Fig. 3.4** The magnitude of electric field distribution on patch surface of CSMA and the corresponding standing wave pattern between the patch and ground plane for two feed-probe positions. (Scales are same in all the plots), (CSMA parameters: radius  $a = 30$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.) (a) CSMA with  $\phi_0 = 45^\circ$  fed along  $\phi = 0^\circ$  line, (b) CSMA with  $\phi_0 = 45^\circ$  fed along  $\phi = \phi_0/2$  line, (c) CSMA with  $\phi_0 = 110^\circ$  fed along  $\phi = 0^\circ$  line, (d) CSMA with  $\phi_0 = 110^\circ$  fed along  $\phi = \phi_0/2$  line. (e) CSMA with  $\phi_0 = 150^\circ$  fed along  $\phi = 0^\circ$  line, (f) CSMA with  $\phi_0 = 150^\circ$  fed along  $\phi = \phi_0/2$  line.

For the cases when the CSMA is fed along the central symmetrical line or along the edge, it confirms the aforementioned observation. The corresponding standing wave distributions between the patch and ground plane have also been indicated in the same figure which corroborates the above explanations of different resonating profiles for the CSMA as a function of azimuthal feed probe locations  $\phi_f$ . This indeed, substantiates that, the fields beneath the patch resonates laterally along  $y$ - $y'$  direction which gives birth to  $y$  polarized electric fields for all edge fed CSMA (fed along or near  $\phi_f = \phi = 0^\circ$  line). In that case, the resonating dimension of a CSMA is along the circumference and hence the length of the arc is nearly half wavelength i.e  $\rho\phi_0 \approx \lambda_g/2$ . On the contrary, the fields beneath the patch resonate longitudinally along the  $x$ - $x'$  direction that gives birth to  $x$  polarized electric fields for the centrally fed CSMA except those with  $110^\circ < \phi_0 \leq 170^\circ$ . For CSMA with  $60^\circ < \phi_0 \leq 110^\circ$ , the resonating dimension of the CSMA is the length of the radial dimension i.e  $\rho = \lambda_g/2$ . In case of the centrally fed CSMA with  $110^\circ < \phi_0 \leq 170^\circ$ , the fields resonates along both the lateral and longitudinal direction and hence produces a mixed polarization and hence not useful for linearly polarized applications. It is also clearly observed in Fig. 3.4 that in all the cases, the feed-probe is to be located between successive minima and maxima standing wave patterns of the corresponding excited mode. Hence, it may be concluded that, to excite the proper lowest order dominant mode of a CSMA, it should be fed near the edge (along  $\phi = 0^\circ$  line). Nevertheless, feeding along the  $\phi = 0^\circ$  line is difficult from practical point of view. Therefore, a rigorous investigation has been performed to find the position (azimuth) up to which the CSMA can be fed to excite its lowest order dominant mode. Each CSMA of different sector angles have been studied through simulation and it is noted that, in each case, the lowest order dominant mode for a particular sector can surely be excited up to  $\phi_f = 0.20\phi_0$ . Although, the optimization of feed location along the central symmetrical  $\phi = \phi_0/2$  line is easy, a CSMA with sector angle  $60^\circ < \phi_0 \leq 170^\circ$  should not be fed along the central symmetrical  $\phi = \phi_0/2$  line, as it excites the next higher order mode rather than the proper dominant mode. It may be noted that all the observations are similar for different substrate heights of the CSMA.

### 3.4 Determination of Approximate Feed Location

In all the cases investigated above; Eq. (3.5) is utilized to investigate the range of  $(E/\omega\mu H)$  ratio for which the dominant mode is excited. It is observed that the impedance of the CSMA varies both along the radial distance and azimuth angle. This in turn develops complexity in finding proper feed location to excite the proper lowest order mode.

(a)

(b)

**Fig. 3.5** Predicted radial feed location ( $\rho_f$ ) ranges of  $120^\circ$  CSMA of  $a = 10$  mm,  $15$  mm,  $20$  mm based on Eq. (3.5) and  $(E_z/\omega\mu H)_{\max}$  (obtained from Eq. (3.5) by putting  $\rho = a$ ) for (a)  $\phi_f = 5^\circ$ , (b)  $\phi_f = 10^\circ$ .

The range of radial feed location  $\rho_f$  for  $\phi_f = 5^\circ$  and  $\phi_f = 10^\circ$  is different for a CSMA with particular radial dimension  $a$ . Till date, no accurate impedance formulation for a CSMA is available from which a particular  $50 \Omega$  point can be determined. Hence, the  $E/H$  ratio has been exploited to find a proper feed location for exciting a particular mode. In fact, the input voltage to current ratio (input impedance) of the patch must contain the signature of the  $E/H$  ratio at that particular point beneath the patch.

It is observed that the  $(E_z/\omega\mu H)$  ratio for which the CSMA is excited at a particular mode varies within a particular range and that is approximately from  $0.15(E_z/\omega\mu H)_{\max}$  to  $0.35(E_z/\omega\mu H)_{\max}$  maximum radial dimension of a CSMA).

Therefore, using Eq. (3.5) an approximate range of feed location can be predicted across which a particular mode can be excited. Therefore, using the same concept, a  $120^\circ$  CSMA with three different radial dimensions have been investigated for two feed locations (in terms of azimuth), namely,  $\phi_f = 5^\circ$  and  $\phi_f = 10^\circ$ , and they are presented in Fig. 3.5. It is observed that the range of feed locations to excite its dominant mode are different for the same patch with feed locations at  $\phi_f = 5^\circ$  and  $\phi_f = 10^\circ$ . For further corroboration of the observation, the approximate range of feed positions is determined (using Eq. (3.5)) for a CSMA with different  $\phi_0$ , and are presented in Table 3.1. Notably, the simulated resonant frequencies and its corresponding  $S_{11}$  values are also incorporated in the table to validate the excitation of the dominant and next higher order modes within the predicted range of feed locations. The theoretical prediction shows good agreement with simulation.

### 3.5 Experimental Results and Discussions

The experiments were carried out with the prototypes having patch radial dimension  $a = 29.7$  mm fabricated on thin PTFE substrate ( $\epsilon_r = 2.33$ , thickness  $h = 1.58$  mm). The patch is fed by an SMA feed-probe (Radiall R125.403.000) with probe diameter of 1.2 mm. One sample of fabricated prototype of a CSMA with  $\phi_0 = 110^\circ$  is presented in Fig. 3.6. Microstrip patch with thin substrate has been preferred to avoid the complexity in feed inductance which causes problem in optimal matching.

Some representative measured results of reflection coefficient profiles are presented in this section.

**TABLE 3.1** Predicted feed-probe positions for a CSMA with different sector angles for excitation of particular modes. (CSMA parameters: radius  $a = 30$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.),  $f_r$ : Resonant frequency of particular mode,  $\phi_f$ : Feed angle in terms of azimuth. Range of  $(E_z/\omega\mu H)$ :  $0.15(E_z/\omega\mu H)_{max}$  to  $0.35(E_z/\omega\mu H)_{max}$ .

In Fig. 3.7, the theoretically predicted feed location range of a CSMA with  $\phi_0 = 110^\circ$  to excite the dominant  $TM_{1.63\ 1}$  mode has been examined through measurements for azimuthal feed angle  $\phi_f = 10^\circ$ . The antenna has been tested for four different radial feed locations  $\rho_f$  and two of them are within the predicted range, while the

others are outside the range. Thus, the predicted feed location range is in good agreement with the measurements.

(a)

(b)

**Fig. 3.6** Fabricated prototype of CSMA with  $\phi_0 = 110^\circ$  (a) top and (b) back view.

In Table 3.2, the excited modes and their measured resonant frequencies of a CSMA with different sector angles ( $\phi_0 = 45^\circ, 60^\circ, 90^\circ, 110^\circ, 150^\circ$  and  $160^\circ$ ) are presented for theoretically predicted feed locations. In each case, the approximate ranges of radial feed locations  $\rho_f$  for specific azimuthal feed angle  $\phi_f$  are determined based on the theoretical prediction presented in section 3.2.1 and section 3.2.2. The experimental radial feed position  $\rho_f$  at same feed angle  $\phi_f$  for every sector angle  $\phi_0$  along with the excited mode and its frequency are presented in Table 3.2. In all the cases, the experimental and simulated feed locations are in good agreement with the theoretically predicted range to excite a particular mode. Each CSMA with a specific

sector angle is fed at different feed locations; in which some are near the edge lines (near and along  $\phi = 0^\circ$  line) and some are at  $\phi_f > 0.2 \phi_0$ . Based on the theoretical predictions, the CSMA s are fed to excite dominant or next higher order modes.

**Fig. 3.7** Comparison of measured and simulated  $S_{11}$  profiles for CSMA with  $\phi_0 = 110^\circ$ ,  $\phi_f = 10^\circ$  at theoretically predicted radial feed locations  $\rho_f$  (CSMA parameters: radius  $a = 30$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.)

It confirms that the excited modes for CSMA s with sector angle  $\phi_0 = 45^\circ$  and  $60^\circ$  are not dependent on the azimuthal feed positions that validate the observation presented in section 3.3.1. Moreover, in both the cases, the excited mode ( $TM_{01}$ ) and its frequency is similar ( $\sim 3.7$  GHz). Therefore, it confirms that the lowest order mode and its frequency of a CSMA with  $\phi_0 \leq 60^\circ$  is independent of sector angle  $\phi_0$ , and its frequency is exclusively dependent on the radial dimension of the patch, as well as the dielectric constant of the substrate. In the cases of CSMA s with  $\phi_0 = 90^\circ$  and  $110^\circ$ , the excited modes significantly depend on the azimuthal feed locations. In these cases, when the CSMA s are fed within  $0.2 \phi_0$ , the lowest order modes are excited. However, the lowest order modes are different in each case and it depends on the sector angle  $\phi_0$  of the CSMA.

**TABLE 3.2** Comparison between predicted and measured feed-probe positions to excite a particular mode and corresponding resonant frequencies for CSMA with different sector angles. (CSMA parameters: radius  $a = 30$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.)

Consequently, the frequencies of the excited lowest order modes are different. The dominant mode resonant frequencies also depend on the sector angle, radial dimension of the patch, as well as the dielectric constant of the substrate. However, when the same CSMA's ( $\phi_0 = 90^\circ$  and  $110^\circ$ ) are fed beyond  $0.2 \phi_0$  or fed centrally; the next higher mode  $TM_{01}$  will be excited. The higher order mode is same in these cases and independent of the sector angle  $\phi_0$  and its frequency is exclusively dependent on the radial dimension of the patch, as well as the dielectric constant of the substrate. Hence, these phenomena of CSMA's with  $60^\circ \leq \phi_0 \leq 110^\circ$  agree with our predictions presented in section 3.3.2. Similar observations are revealed for CSMA's with  $\phi_0 = 150^\circ$  and  $160^\circ$ . However, such CSMA's when centrally feed ( $\phi_f = 0.5\phi_0$ ) or feed at  $\phi_f > 0.2 \phi_0$  excite different higher order modes and this is a key difference with CSMA's

with  $60^\circ < \phi_0 \leq 110^\circ$ , as have been discussed in section 3.3.2. Moreover, the next higher order modes are  $TM_{21}$  instead of  $TM_{01}$  mode.

Nevertheless, it is very clear from the investigation that the dominant mode for a CSMA with specific sector angle (with  $\phi_0 > 60^\circ$ ) can be excited only up to  $\phi = 0.2 \phi_0$ . When the same CSMA is fed at  $\phi_f > 0.2 \phi_0$  and typically along central line i.e  $\phi_f = 0.5 \phi_0$ ; the dominant modes are not excited. Instead, the next higher mode will be excited. In each of the cases in Table 3.2, it is revealed that within the predicted feed location ranges, the experimental and simulated feed-probe locations for the excitation of specific mode are in excellent agreement.

(a)

(b)

(c)

**Fig. 3.8** Measured  $S_{11}$  profile for a CSMA with different sector angles fed along different  $\phi$  line. (CSMA parameters: radius  $a = 29.7$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.), (a) sector angle  $\phi_0 = 45^\circ$ , (b) sector angle  $\phi_0 = 90^\circ$ , (c) sector angle  $\phi_0 = 150^\circ$ .

However, for centrally fed CSMAs with sector angles of  $120^\circ \leq \phi_0 \leq 170^\circ$ , the approximate range of feed locations has not been predicted with the present theory as they produce different higher order modes with complex field configuration. The  $S_{11}$  profiles for some of the cases shown in Table 3.2 for different feed probe locations are presented in Fig. 3.8. This gives a clear visualization of varying  $S_{11}$  profiles as a function of feed probe locations in a CSMA with  $\phi_0 = 45^\circ$ ,  $90^\circ$  and  $150^\circ$ . Hence, it is observed from measurements that in all the cases, the feed locations to excite a particular mode in a specific CSMA with specific sector angle  $\phi_0$  can be predicted easily with the help of the proposed technique.

Hence the influence of the feed-probe as a function of modes of CSMA has been investigated thoroughly. The particular position of feed probe to excite particular mode including the lowest order dominant mode has been established. The radiation characteristic of CSMA as a function of feed position is equally important and has been documented in the following section.

### 3.6 Radiation Characteristics of CSMA as a Function of Feed Position

The radiation characteristics of  $90^\circ$  CSMA for two feed positions have been investigated further. The CSMA with a small sector angle  $\phi_0 = 90^\circ$  has been considered in the present investigation in view of lesser space requirement compared to CMA. As observed from section 3.3.2,  $90^\circ$  CSMA has the lowest order dominant  $TM_{21}$  and that can only be excited when it is fed along its edge. If the  $90^\circ$  CSMA is fed along central symmetrical line, it excites next higher  $TM_{01}$  mode. Therefore, depending on the feed probe location, two modes can be excited as Antenna#1 (feed probe along central symmetrical line,  $\phi = \phi_0/2$ ) and Antenna #2 (feed probe along central symmetrical line,  $\phi = 0^\circ$ ). Based on theory presented in section 3.4 Antenna#2 is fed at  $\phi_f = 5^\circ$  and  $\rho_f = 5$  mm. The simulated field distribution for Antenna#1 and Antenna#2 has been depicted in Fig. 3.9. The figure confirms the proposed analysis documented up to section 3.5. If the  $90^\circ$  CSMA is fed along central symmetrical line, it excites next higher  $TM_{01}$  mode. Therefore, depending on the feed probe location, two modes can be excited as Antenna#1 (feed probe along central symmetrical line,  $\phi = \phi_0/2$ ) and Antenna#2 (feed probe along central symmetrical line,  $\phi = 0^\circ$ ). Based on theory presented in section 3.4 Antenna#2 is fed at  $\phi_f = 5^\circ$  and  $\rho_f = 5$  mm. The simulated field distribution for Antenna#1 and Antenna#2 has been depicted in Fig. 3.9. The figure confirms the proposed analysis documented up to section 3.5.

(b)

**Fig. 3.9** The magnitude of simulated [18] electric field distribution over patch surface of CSMA for two feed-probe positions. (CSMA parameters: radius  $a = 10$  mm,  $\epsilon_r = 2.33$ , substrate height  $h = 1.575$  mm.) (a) CSMA with  $\phi_0 = 90^\circ$  fed along  $\phi = \phi_0/2$  line (b) CSMA with  $\phi_0 = 90^\circ$  fed along  $\phi = 0^\circ$  line.

### 3.6.1 Antenna#1: $90^\circ$ CSMA with Feed -Probe along Central Symmetrical $\phi = \phi_0/2$ line

The simulated [14] reflection coefficient of Antenna#1 has been presented in Fig 3.10. The Antenna#1 exhibits around 9 % impedance bandwidth.

**Fig. 3.10** Simulated reflection co-efficient profile for Antenna#1 (center fed  $90^\circ$  CSMA)

The H plane and E plane co-pole radiation pattern are presented in Fig. 3.11. It is observed that the Antenna#1 show broadside radiation pattern and have good radiation characteristics. The 3dB beam widths of both the antennas are around  $70^\circ$  and  $95^\circ$  in H and E-plane, respectively

**Fig. 3.11** CP Radiation patterns for Antenna#1 at  $TM_{01}$  mode ( $f_r = 10.59$  GHz) in both E and H plane

### 3.6.2 Antenna#2: $90^\circ$ CSMA with Feed -Probe along Edge ( $\phi = 0^\circ$ line)

Now, the same CSMA is fed along edge ( $\phi = 5^\circ$  line) by a feed-probe. It is observed that instead of  $TM_{01}$  mode, dominant  $TM_{21}$  mode is excited. It is further observed that  $TM_{21}$  is excited up to the feed-probe position  $\phi_1 = 30^\circ$  line and beyond that this mode ceases to exist. The simulated [18] reflection coefficient is presented in Fig 3.12. The CSMA exhibits around 5% impedance bandwidth. The simulated [18] CP E plane and H plane radiation patterns are presented in Fig. 3.13.

**Fig. 3.12** Simulated reflection co-efficient profile for Antenna#2 (edge fed 90° CSMA)

**Fig. 3.13** CP Radiation patterns for Antenna#2 at  $TM_{21}$  mode ( $f_r = 8.8$  GHz) in both E and H plane.

### 3.7 An Attempt to Enhance of Gain in CSMA

The study of gain enhancement of  $90^\circ$  CSMA has not been reported earlier. Thus, the study of gain improvement is important to understand the radiation characteristics of CSMA. The detailed study of improvement of gain in  $90^\circ$  CSMA has been discussed in this section. Although the  $90^\circ$  CSMA attains miniaturization, gain of such antenna is not satisfactory in comparison with conventional CMA. However, gain improvement is one of the primary requirements of modern antenna technology. Therefore, the gain can be enhanced in such antennas if the conventional dielectric substrate (PTFE) is replaced by simple air substrate. Although several attempts have been made to use CSMA in modern wireless communications for different applications, the issue of gain enhancement in such small antennas has not been properly addressed in the open literatures. The use of air substrate in microstrip antennas of common geometries is the common and popular technique to enhance the gain.

In this section, the air substrate has been utilized instead of PTFE substrate and an improvement of gain is observed like other geometries. Further, a quick hand formulation has been established to estimate the gain enhancement of CSMA with air substrate compared to standard CSMA on PTFE substrate. In this present study, a edge fed  $90^\circ$  CSMA ( $\phi_0 = 90^\circ$ ) of radius  $a = 30$  mm on PTFE ( $\epsilon_r = 2.33$ ) and air substrate ( $\epsilon_r = 1$ ) with  $h = 1.575$  mm has been investigated on  $60 \times 60$  mm<sup>2</sup> ground plane. Both the antennas excite its dominant  $TM_{21}$  mode as discussed in the earlier section of this chapter. The schematic representation of the structure is shown in Fig. 3.14.

The change in gain ( $\Delta G$ ) and effective radiating area ( $A_{eff}$ ) of a microstrip patch antenna is related as follows.

$$\Delta G[dB] = 10 \log_{10} \left[ \frac{\left( \frac{A_{eff}}{\lambda_0^2} \right)_{air}}{\left( \frac{A_{eff}}{\lambda_0^2} \right)_{ref}} \right] \quad (3.8)$$

where,  $A_{eff} = \frac{(a_{eff}^2 \phi_0)}{2}$  for CSMA where  $\phi_0 = 1.57$  radian,

$$a_{eff} = (a \times \sqrt{1 + q}),$$

$q$  = fringing factor and obtained from chapter 2.

$\lambda_0$  = operating wavelength of the respective radiator.

As soon as the conventional PTFE substrate is replaced by air substrate, the electric field becomes loosely bound. It results in wider effective area, and hence provides better gain.

**Fig. 3.14.** Schematic diagram of 90° CSMA (a) top view (b) cross-sectional views.

The simulation study has been carried out using commercially available HFSS (v.14). The reflection coefficient profiles for both the CSMA (with PTFE and air substrates) have been presented in Fig. 3.15. As expected, the resonant frequency of CSMA with air substrate has been shifted towards the higher side of the spectrum in comparison with CSMA on PTFE substrate. The resonant frequency of CSMA with air substrate is around 4.4. GHz while the same with PTFE substrate is around 2.9 GHz. Moreover, the bandwidth in case of the air substrate is better (6% more) as compare to PTFE substrate.

**Fig. 3.15** Reflection coefficient profile of 90° CSMA with PTFE substrate and air substrate

**Fig. 3.16** Radiation pattern (co-pol and cross-pol) of CSMA with PTFE substrate

**Fig. 3.17** Radiation pattern (co-pol and cross-pol) of CSMA with air substrate

It is observed that the co-pol gain of CSMA with air substrate is around 9.9 dBi whereas; the same with PTFE substrate is only 7.1 dBi. 2.8 dBi of gain improvement is revealed from the proposed technique.

The comparison of simulated and calculated gain enhancement of CSMA with air substrate has been presented in Table 3.3. A close agreement has been revealed between computed and simulated result.

**TABLE 3.3** The calculated values of the effective patch dimensions and gain enhancement compared with the measured results.

| Substrate | Resonance frequency (GHz) | Effective radial dimension ( $a_{eff}$ ) | Simulated gain (dBi) | $\Delta G[dB]$ |            |
|-----------|---------------------------|--|----------------------|----------------|------------|
|           |                           |  |                      | Simulated      | Calculated |
| PTFE      | 2.92                      | 32.49                                    | 7.1                  | 2.8            | 3.14       |
| Air       | 4.43                      | 33.94                                    | 9.9                  |                |            |

### 3.9 Conclusion

The influence of the feed-probe on the modes of CSMA has been investigated thoroughly and methodically. The fractional / dominant mode as well as the higher

order modes as a function of feed location in the CSMA with different range of sector angles from  $0^0$  to  $170^0$  has been categorized and discussed in detail. The polarization of those has also been explained with the help of standing wave patterns observing beneath the patch. Finally, based on maximum  $E/H$  ratio an accurate but quick hand approximate theoretical technique has been anticipated to determine the feed location of a CSMA which can excite a specific mode. Consequently,  $90^0$  CSMA with air and PTFE substrate has also been thoroughly investigated for gain enhancement. A quick hand formulation has also been developed to estimate the gain enhancement which is in close agreement with simulated results. The proposed techniques to estimate the gain enhancement for CSMA with air substrate is very easy and simple which will be surely beneficial for scientist and practicing engineers looking for high gain simple CSMA. As such, the design issues of CSMA and determination of modes are critical and complex. The issue of miniaturization with respect to the radial dimension and active patch area is vital to choose a specific sector angle of CSMA. Therefore, compact design issues are very important for practicing and design engineers which will be discussed in the next chapter.

## Compact Design Guidelines for the Choice of Sector Angle of Circular Sector Microstrip Antenna

### 4.1 Introduction

The modal analysis, excitation of modes as function of feed location and radiation characteristics of circular sector microstrip antenna (CSMA) having various types of sectoral angle has been discussed in previous chapters. The issues related to numerous sector angles of CSMA have been discussed thoroughly. As such, because of asymmetric geometry of CSMA, it has a special feature to excite numerous modes including fractional modes that depend on sector angle and feed probe location. Therefore, it is necessary to have a suitable CSMA structure which will be applicable in all perspective. A systematic study has been carried out in this chapter for exact choice of sector angle as a better alternative of a circular microstrip antenna. Therefore, comprehensive design guidelines are provided to estimate best possible configuration at any specific application.

Notably, there are much application e.g in mobile communication base terminal for microcellular system; antenna is mounted in same substrate for active microwave components [1]. In most of the cases, CSMA with large sector angle ( $\phi_0 \geq 180^\circ$ ) has been investigated. However, CSMA with sector angle ( $\phi_0 \leq 180^\circ$ ) is preferable to keep the other electronics circuits beside the antenna. Typically, the advanced wireless services (AWS-2), the broadband PCS, cable antenna relay service, uses the lower range of microwave band i.e., 1-2 GHz [2]. Further, modern sub-6 GHz 5G applications are also limited from 2-6 GHz. Therefore, any array or 5G MIMO

configuration, individual radiators should be small enough to mount on limited space. Notably, sub-6 GHz MIMO antennas are purely linearly polarized [3]. At this stage, CMA takes large space than CSMA. Moreover, the low frequency CMAs resonating specially below 3-4 GHz has high cross polar (XP) radiation which makes the co-polar (CP) radiation vulnerable. At this present scenario appropriate selection of CSMA is required to develop the miniaturized printed antenna as a suitable replacement of conventional CMA. Therefore, the critical design issues of CSMA definitely demands noteworthy attention to the scientific community to design such antennas.

(a)

(b)

(c)

(d)

**Fig. 4.1** (a) Schematic representation of CSMA of included angle  $\phi_0$ , (b) top view fabricated prototype of  $170^\circ$  CSMA, (c) fabricated prototype of the equivalent circular patch, (d) bottom view of both prototypes.

At present, the investigation on CSMA geometry for widespread applications have been reported as it reveals extra compactness and conformality over bent

surfaces. Recently, proximity coupled CSMA with large sector angle ( $\phi_0$ ) such as  $270^\circ$ ,  $300^\circ$ ,  $320^\circ$  &  $340^\circ$  etc have been reported [4], [5] for broad banding of patch. Novel dual mode dual stub loaded wideband  $270^\circ$  CSMA has been investigated in [6] where, higher order modes are utilized. Some more experimental investigations [7]-[8] have been reported for yielding circular polarization, Ku band applications. Employment of metamaterial in CSMA has been reported in [9] for obtaining quasi mono-polar pattern. However, all such investigations were based on simulation and the measurements were carried out to validate the proof of concept.

The resonance frequency formulation of CSMA using cavity model has been documented in chapter 2. The investigation into the influence of the feed-probe on the modes of CSMA has been discussed thoroughly in chapter 3. The radiation characteristics in CSMA and the employment of air substrate in CSMA to enhance the gain have been carried out in same chapter.

In this chapter it is aimed to develop comprehensive design guidelines for the selection of CSMA antenna geometry thoroughly, indicating the possibilities and limitations. Primarily, rigorous calculations are carried out and validated through measurements and simulation. Based on design guidelines, prototypes of  $170^\circ$  CSMA and conventional CMA have been fabricated for 1.86 GHz frequencies are fabricated, and their typical results are compared, which revealed that the  $170^\circ$  CSMA offers better radiation performance than the Conventional circular microstrip antenna (CCMA). The chapter has been organized in the following way. Section 4.2 has been described about the design consideration of CSMA in view of tininess. Selection of sector angle  $\phi_0$  in based on operating mode and frequency has been presented in section 4.2.1. Selection of sector angle  $\phi_0$  in based on miniaturization has been described and compared with respect to CMA in section 4.2.2. The discussion of experiential result has been verified in section 4.3. Finally, the best choice of sector angle  $\phi_0$  has been prescribed in section 4.4.

## **4.2 Design Consideration**

In the present investigation, at first, the selection of lowest order frequency and operating mode of CSMA for any included angle  $\phi_0$  has been carried out in view of miniaturization. The close inspection of CSMA geometry depicts that, it demands a

special boundary condition which is not similar to conventional CMA. That is, the vanishing radial component of magnetic field boundary condition for vector potential wave equation at two truncated edges along  $\phi$  i.e

$$H_{\rho}(\phi = 0) = \frac{1}{\mu} \frac{1}{\rho} \frac{\partial A_z}{\partial \phi} = \frac{1}{\mu} \frac{1}{\rho} B_{mnp} J_m(k_{\rho} \rho) [-mA \sin m\phi + mB \cos m\phi] [\cos(k_z z)] = 0 \quad (4.1)$$

Where,  $m$  is the mode number of CSMA of specific sector angle while,  $A$  and  $B$  are the constants and these can be determined from vanishing magnetic field boundary condition as is discussed in chapter 2. Following the theoretical formulation developed in chapter 2, it can be written as

$$m\phi_0 = q\pi \Rightarrow m = \frac{q\pi}{\phi_0} \quad (4.2)$$

where  $q = 0, 1, 2, 3$ , any positive integers.

It may be noted that, the determining factor of mode number  $m$  is dependent on the sector angle  $\phi_0$  and the number of circumferential field variation  $q$ . Although, this  $q$  is in integer form, the mode number  $m$  of CSMA of angle  $\phi_0$  is fractional. Therefore, CSMA can exhibit fractional modes depending on the chosen sector angle  $\phi_0$ .

#### 4.2.1 Selection of Sector Angle $\phi_0$ in View of Operating Mode and Frequency

The dominant mode resonance frequency of CSMA can be written from chapter 2

$$f_r = \frac{\chi'_{mn} c}{2\pi a_s \sqrt{\epsilon_{\text{reff}}}} \quad (4.3)$$

where,  $c$  is the free space velocity and  $a_s$  is the radial dimension of CSMA. The effective dielectric constant is  $\epsilon_{\text{reff}}$  and  $\chi'_{mn}$  is the  $n^{\text{th}}$  root of derivative of Bessel function of order  $m$  (mode number). It is observed that, numerous values of mode numbers  $m$  are possible as there are plentiful numbers of possible sector angles  $\phi_0$  in between  $0^\circ$  to  $360^\circ$  in case of CSMA. Notably, the mode number  $m$  may also be fractional in many cases.

**Fig. 4.2** (a) Possible mode number  $m$  and  $\chi'_{mn}$  values for all possible sector angles of CSMA, (b) The resonant frequency of the CSMA ( $a_s = 30$  mm) with different sector angles  $\phi_0$  and the corresponding radial dimension  $a_c$  for CCMA.

Also, the lowest  $\chi'_{mn}$  value is responsible to excite the dominant mode frequency of CSMA. Therefore, mode number  $m$  is very crucial to determine the operating frequency of CSMA. The possible mode numbers  $m$  and the corresponding  $\chi'_{mn}$  values are depicted in Fig. 4.2 (a) for the CSMA of any sector angle  $\phi_0$ . In this figure, the proper dominant mode and its resonant Frequency may be obtained with the help of equation (4.3). From the Fig. 4.2 (a), it is observed that up to sector angle

$\phi_0 = 68^\circ$ , the mode number  $m$  is independent of CSMA sector angle ( $\phi_0$ ) and it is zero.

Therefore,  $\chi'_{mn}$  and the resonant frequency, are same for all sector angles from  $\phi_0 \rightarrow 0^\circ$  to  $\phi_0 \rightarrow 68^\circ$ . In this range of sector angles, the radial dimension  $a_s$  is the main determining factor for the resonant frequency of CSMA at its dominant  $TM_{0l}$  mode. It also reveals from the figure that any sector angle, beyond  $\phi_0 = 68^\circ$ , mode number ( $m$ ) decreases and  $\chi'_{mn}$  decreases. Therefore, resonant frequency shifts from one sector angle to another and may be determined from the modal chart (Fig. 4.2 (a)).

#### 4.2.2 Selection of Sector Angle $\phi_0$ in View of Miniaturization

The vital requirement of miniaturization comes in relation to the low frequency operations. Therefore, to excite the frequency below 5 GHz, the required patch dimensions in case of conventional CMA is large enough. Therefore, to excite lower frequency, the radial dimension of CSMA is chosen as  $a_s = 30$  mm on standard PTFE substrate of permittivity  $\epsilon_r = 2.33$  and thickness  $h = 1.575$  mm.

In order to excite same resonant frequency  $f_{rs}$  in CSMA (radial dimension  $a_s$ ) and  $f_{rc}$  in CMA (radial dimension  $a_c$ ),

$$f_{rs} = \frac{\chi'_{mn}c}{2\pi a_s \sqrt{\epsilon_r}} = \frac{1.84c}{2\pi a_c \sqrt{\epsilon_r}} = f_{rc} \Rightarrow a_c = \left( \frac{1.84}{\chi'_{mn}} \right) a_s \quad (4.4)$$

equation (4.4) may be used to compare the required radial dimension of CMA and CSMA to excite a specific frequency. The resonant frequency of CSMA ( $a_s = 30$  mm) of numerous sector angles  $\phi_0$  has been plotted in Fig. 4.2 (b). To excite the same frequency the corresponding radial dimension of circular patch ( $a_c$ ) has also been given in same plot for comparison. The figure reveals that, if  $\phi_0$  varies from  $5^\circ$  to  $359^\circ$  in CSMA, with fixed  $a_s (= 30$  mm) on traditional PTFE substrate, the operating frequency varies from 3.69 GHz to 1.18 GHz. It may be noted that, up to  $\phi_0 = 68^\circ$ , the operating frequency is independent of sector angle for CSMA and it always excites same mode ( $m = 0$ ) with same frequency 3.69 GHz. Consequently, the radial dimension of CMA is fixed to 14.9 mm. Immediately after  $\phi_0 > 68^\circ$ ,  $f_r$  of same CSMA suddenly decreases to 2.12 GHz and then continue to decrease up to 1.18 GHz gradually with the sector angle  $\phi_0$ . Consequently, required radial dimension of

CMA ( $a_c$ ) starts to increase from 14.9 to 47.3 mm. Fig.4.2(b) depicts that, up to  $180^\circ$ , the required radial dimension of CMA is lesser than that of CSMA ( i.e.  $a_c < a_s$ ) and the situation gets reverse (i.e.  $a_c > a_s$ ) when  $\phi_0 > 180^\circ$ .

The required areas for CCMA is denoted as  $A_c$  while the same for CSMA is  $A_s$

$$A_c = \pi a_c^2 \quad (4.5)$$

$$A_s = \phi_0 \frac{a_s^2}{2} = 0.15\phi_0 (\chi'_{mn})^2 a_c^2 \quad (4.6)$$

**Fig. 4.3** Comparison of absolute patch area of CSMA and equivalent CCMA (both resonating at the same frequency) and the percentage of patch area reduction of CSMA in comparison to equivalent CCMA.

Therefore, the CSMA area is dependent on the sector angle  $\phi_0$ ,  $\chi'_{mn}$  and obviously on mode number  $m$ . However, the rigorous investigation of  $\chi'_{mn}$  values show that the smaller value of  $a_c$  than  $a_s$  (for  $\phi_0 < 180^\circ$ ) does not help much in the reduction of patch radiating area (due to much smaller  $\phi_0$  value in respective CSMA) and as a result, the CMA radiating area is still greater than CSMA with specific  $\phi_0$  and obeys  $A_c > A_s$ .

The absolute patch radiating area for CMA and CSMA for above case is presented in Fig. 4.3. It shows that, the patch area is always greater for CMA in comparison to CSMA. The % area reduction of CSMA in comparison to CMA is also depicted in Fig. 4.3. It confirms that, the area of CSMA is always smaller than CMA except  $\phi_0 = 68^\circ$ . Therefore,  $68^\circ$  CSMA offers no apparent advantage over

CMA as both the radiators have similar radiating area. Notably, as  $\phi_0 \neq 68^\circ$ , the required patch area of CSMA become smaller than CMA. Although, the percent (%) area reduction of CSMA with very small  $\phi_0$  is high (around 65%) still, such small sector antenna may exhibit very poor radiation efficiency and hence avoidable to use in place of CMA.

Again, it is apparent that if  $\phi_0 > 180^\circ$ , patch area reduction is around 55-60%. However, for  $\phi_0 > 180^\circ$ , the physical geometry of CSMA becomes much border and it is difficult to keep associated circuitry beside the antenna structure in tiny electronic devices. Therefore, it is preferred to use CSMA with  $\phi_0$  either  $180^\circ$  or slightly lesser than  $180^\circ$  as it has equivalent radial dimension of CMA but with a patch are reduction of 50%. Therefore,  $\phi_0 = 170^\circ$  CSMA has been chosen for experimental validation of radiation characteristics in the next section.

### 4.3 Experimental Result & Discussion

The fabricated prototypes of conventional CMA ( $a_c = 29.5$  mm) and  $170^\circ$  CSMA ( $a_s = 30$  mm) has been measured and compared. The detailed measured radiation parameters are presented in Table 4.1. The measured  $S_{11}$  profile for both the antennas is presented in Fig. 4.4 and it shows exactly similar performance in relation to the input impedance bandwidth. Both the antennas exhibit around 2% bandwidth and are resonance at 1.86 GHz (CMA) and 1.87 GHz (CSMA).

**TABLE 4.1** Measured performance comparison of  $170^\circ$  CSMA and equivalent CCMA

| Antenna Type            | % Impedance bandwidth | Pattern Profile | Gain (dBi) | Beam Width (degree) |         | Efficiency (%) |
|-------------------------|-----------------------|-----------------|------------|---------------------|---------|----------------|
|                         |                       |                 |            | E plane             | H plane |                |
| Conventional CMA        | 2%                    | Broadside       | 5.27       | 82                  | 84      | 88%            |
| $170^\circ$ Sector CSMA | 1.8%                  | Broadside       | 5.7        | 74                  | 90      | 92%            |

Comparison of Fig. 4.5 and Fig. 4.6 reveals the similarity in broadside side patterns at E plane for  $170^\circ$  CSMA and conventional CMA. The similar observation has been depicted in Fig. 4.5 and Fig. 4.6 for H plane. In both the cases, simulation results closely agree with the measured results

**Fig. 4.4** The measured  $S_{11}$  profile of  $170^\circ$  CSMA is compare with CMA.

It seems that, the gains, patterns and beam widths of both the antennas are similar. It has seen that co-pole radiation pattern in both the plane is broadside. Therefore, judicious choice of CSMA parameters is very crucial and it is seen that, such  $170^\circ$  CSMA is well-competent to replace classical CMA. The simulated and measured co-pole radiation characteristics for both principal planes are depicted in Fig. 4.5 and Fig. 4.6.

(a)

**Fig. 4.6** The simulated and measured radiation of CP in (a) H plane CMA, (b) H plane CSMA.

#### 4.4 Conclusion

The present study provides complete design guidelines without which it is really complicated to design an efficient CSMA for practical wireless applications. It is shown that, the judicious choice of sector angle is around  $170^\circ$  to  $180^\circ$  to miniaturization as well as better radiation performance. Further, efficient design of CSMA can offer better performance in comparison to classical circular patch and hence, relatively larger patch may be replaced with such CSMA.

## **A New Design Approach to Minimize the Cross Polarization of Circular Sector Microstrip Antenna**

### **5.1 Introduction**

The input characteristics of wide variety of sector angles of circular sector microstrip antenna (CSMA) and its comprehensive design guideline have been discussed in the earlier chapters. As per the discussions of chapter 4, CSMA with  $170^\circ$  to  $180^\circ$  sector angle is the obvious choice in view of miniaturization of microstrip antenna. Further, to keep the associated circuitry beside the antenna, CSMA with such sector angles are very much beneficial for antenna community looking for miniaturized antenna.  $170^\circ$  sector angle has been experimentally investigated in previous chapter. However, designing such  $170^\circ$  CSMA is still complex in comparison to  $180^\circ$  CSMA.  $180^\circ$  CSMA is also good in terms of miniaturization as is documented in chapter 4. Thus, in this chapter,  $180^\circ$  CSMA has been considered for thorough investigation with a view to germinate a specific CSMA as the replacement of circular microstrip antenna (CMA).

The semicircular patch ( $180^\circ$ ) is very advantageous where the space is the key factor to organize a patch with conventional geometry. In fact, 50% of patch area reduction can be achieved using semicircular patch for a particular resonant frequency compared to conventional CMA. Hence, the accurate determination of mode as well as its radiation performance of a semicircular patch is very important in this scenario. The dominant mode of semicircular patch, its frequency and its radiation characteristic at its lowest order dominant mode have been investigated as thoroughly. The mathematical derivations to determine the accurate dominant mode

frequency are based on modified cavity model along with the accurate estimation of the fringing electric fields and resulting effective antenna dimension as is discussed in chapter 2.

The semicircular CSMA as an alternative of CMA has been presented in section 5.2. The radiation characteristic of  $180^\circ$  CSMA has been discussed in section 5.3. A new design approach has been proposed towards compact  $180^\circ$  circular sector microstrip antenna with low cross polarization in section 5.4. Evolution analysis of the proposed antenna has been presented in section 5.5. Proposed structure has been described in section 5.6. In section 5.7, the proposed design has been validated by simulation and experimental results. Section 5.8 contains the conclusions developed from the findings of the present work.

## 5.2 Semicircular CSMA as an alternative of CMA

A coaxially fed CSMA having radial dimension  $a$ , printed on a PTFE substrate ( $\epsilon_r$ ) with thickness  $h_1$  is shown in Fig. 5.1 The antenna is fed at  $\rho_c$  from centre as shown in the figure using a coaxial probe.

**Fig. 5.1** Schematic representation of semicircular patch (Top View).

From the modal chart of chapter 4, it is found that for semicircular patch the dominant mode is  $TM_{mn}$  where  $m = n = 1$ . Therefore, the semicircular patch is having the same lowest order dominant mode (*i.e.*  $TM_{11}$ ) like conventional circular patch.

**Fig. 5.2** Magnitude of electric field on patch surface to explain the number of field variation in radial and circumferential direction.

Thus, it is interesting to note that, though the geometry of the patch is different, dominant mode is similar for circular and semicircular patch. Therefore, for a particular operating frequency, one need not design the circular patch. Instead, a semicircular patch with 50% reduced patch area can be designed.

The magnitude of electric field over the patch is presented in Fig. 5.2. It is clear from the figure that, the number of field variation either in circumferential or in radial direction is 1. This confirms that the lowest order mode of semicircular patch is same as circular patch and it is  $TM_{11}$ .

### 5.3 Radiation characteristics of 180° CSMA

At first, the fundamental radiation characteristics of 180° CSMA has been studied. The radiation characteristics of corresponding CMA has also been investigated for comparison. The co-polar (CP) and cross polar (XP) radiation characteristics of both the CSMA (180°) and equivalent CMA is portrayed in Fig.5.3. Both the antennas produce similar CP radiation beam at its broadside direction. It has been found from Fig. 5.3 that the gain of both the patches is around 6.4 dBi. However, there is significant degradation of XP radiation performance for 180° CSMA, in comparison

to equivalent CMA. Specifically, the profile of XP radiation beam is broadside in case of  $180^\circ$  CSMA while the same for conventional equivalent CMA is conical.

**Fig. 5.3** The comparison between radiation properties of circular and semicircular patch in H planes.

It may be noted that, the conical XP profile is very much required than broadside XP profile for patch antennas. This is because, the conical XP profile doesn't have significant radiation of cross field at bore sight where main CP-beam maxima exists. Contrarily, the broadside XP profile produce significant cross field radiation at the bore sight and have the main CP beam gets affected. Therefore, the main challenge of the present investigation is to shape the XP beam profile of  $180^\circ$  CSMA from broadside to conical. The isolation between peak CP and peak XP gain is noted as cross polarization discrimination (XPD). The XPD of  $180^\circ$  CSMA at the bore sight direction is around 16 dB while the same for equivalent conventional CMA is around 23 dB. Therefore, the XPD is not at all satisfactory for  $180^\circ$  CSMA in comparison to conventional CMA.

Therefore, moderate radiation performance is revealed for semicircular patch compared to that of circular patch. Therefore, it is concluded that a patch of semicircular geometry with 50% reduced patch area may be an alternative to a patch

of conventional circular geometry. But polarisation purity of this sectoral antenna has to be high to make it as an efficient compact antenna.

In the next session a new design approach has been documented towards compact  $180^\circ$  circular sector microstrip antenna with low cross polarization.

#### **5.4 Design Approach Towards Cross Pole Miniaturization by Defected Patch Surface (DPS).**

Circular sector microstrip antenna (CSMA) with relatively smaller sector angle ( $\phi_0=180^\circ$ ) is an excellent preference over circular microstrip antenna (CMA) [1]-[4]. Earlier, rectangular microstrip antenna (RMA) and CMA were widely investigated for patch area miniaturization in [5]-[15]. However, such miniaturized antennas suffer from very poor gain [11], bandwidth [9]-[11], and high cross-polar (XP) radiations [9]-[12], squinted E-plane dipole like profile and omnidirectional H-plane profile [13]. CSMA with very large sector angles i.e.  $\phi_0 \sim 270^\circ, 340^\circ$  and  $350^\circ$  have been investigated in [16]-[18] for broad banding or multi banding without any improvement in radiation performance or miniaturization. Further, [19] shows that  $180^\circ$  CSMA offers poor co-polar (CO) to cross polar radiation (XP) isolation (XPD) (around 8 dB) at the X band with a broadside XP pattern instead of a conical XP pattern which affects the main CO profile. Therefore, it is undeniably challenging to modulate the XP profile of  $180^\circ$  CSMA with improved XPD along with achieving miniaturization. It is well-known that linearly polarized CMA and RMA exhibit high XP radiations [1],[4], [20]-[27]. However, common XP radiation minimization techniques for instance, use of modified feed structures, defected ground structures (DGSs), and shorted patch and pins (SP); have not been investigated till date for minimizing XP radiations in CSMA with small sector angle ( $\phi_0 \rightarrow 180^\circ$ ). Notably, a CSMA with sector angle  $\phi_0=180^\circ$  has a thought-provoking feature of exciting similar dominant mode and resonant frequency in comparison with that of a conventional CMA with around 50% patch area reduction. Also, the ground plane dimension becomes a parameter of vital relevance to designing of miniaturized antenna [28].

(a)

(b)

**Fig. 5.4** (a) Schematic representation of proposed antenna (top view), (b) fabricated prototypes over large and smaller ground planes.

Most of earlier reported structures could not show their efficacy as small antenna by circumscribing the patch radiator (including ground plane) within a sphere of radius  $(\lambda/2\pi)$  i.e., Wheeler limit. Therefore, a compact CSMA (with  $\phi_0 = 180^\circ$ ) structure has been proposed, (Fig. 5.4) with improved radiation characteristics, low XP radiation along with miniaturization. Further, the proposed structure exhibits satisfactory performance on very small ground plane also.

### 5.5 Evolution analysis of the proposed antenna

First, a CMA with radius  $a$  was designed over the substrate ( $\epsilon_r = 2.33$ , thickness  $h = 1.575$  mm) at X band that acts as a reference CMA (Antenna#1) (Fig. 5.5 (a)). In step 2, the left half of the patch surface was removed which gave birth to a CSMA with  $\phi_0 = 180^\circ$  (Antenna#2) as shown in Fig. 5.5(b).

**Fig. 5.5** Patch surface evolution (a) Antenna#1 (ref antenna), (b)Antenna#2, (c) Antenna#3, (d) Antenna#4 (final proposed antenna).

The parametric equation for the locus of Antenna#2 can be written as

$$x = a \cos \phi \quad (5.1)$$

$$y = a \sin \psi \quad (5.2)$$

where,  $\phi \rightarrow 0$  to  $\phi \rightarrow 180^\circ$  ( $\phi_0$ ) and  $a = 6$  mm.

As observed from [2]-[3], both the antennas exhibit equivalence in modal characteristics when excited at the same dominant  $TM_{11}$  mode. Antenna#2 resonates at 8.67 GHz.

The modal electric fields beneath the patch (Antenna#2) corresponding to different modes can be written as [2], [3],

$$\frac{E_z}{E_0} = \cos(m\phi) J_m(k_\rho \rho) \cos(k_z z) \quad (5.3)$$

where,  $k_\rho = 1.84/a$  for  $TM_{11}$  mode ( $m=1$ ) and  $k_\rho = 3.05/a$  for higher order  $TM_{21}$  mode ( $m=2$ ). Although, Antenna#2 may be thought of as an alternative of Antenna#1 with 50% patch area reduction (in the view of same excitation mode and frequency), there is a tendency of automatic excitation of higher order orthogonal  $TM_{21}$  mode in Antenna#2. This  $TM_{21}$  mode and the structural asymmetry in Antenna#2 cause massive degradation in XP radiation [20].

(a)

(b)

(c)

**Fig. 5.6** The electric field vector distribution [29] in the substrate at (a)  $TM_{11}$  mode in Antenna#2, (b)  $TM_{21}$  mode in Antenna#2, (c) circumferential and radial variation of edge electric field magnitude for  $TM_{11}$  and  $TM_{21}$  mode.

The electric field vector distribution of  $TM_{11}$  and  $TM_{21}$  modes are depicted in Fig. 5.6 (a) and Fig. 5.6 (b) as a function of  $\phi$  (patch circumferential angle). The E field magnitude distribution as a function of circumferential angle  $\phi$  for  $TM_{11}$  (black) and  $TM_{21}$  (red) modes are presented in Fig. 5.6 (c). The close inspection of Fig. 5.6 (b) and Fig. 5.6 (c) proves that significant XP radiation arises due to the edge electric fields (for  $TM_{21}$  mode; Red curve) existing in the range of  $\phi = 45^\circ$  to  $138^\circ$ .

Further, in that specified range of  $\phi$ , the fringing fields of dominant  $TM_{11}$  mode have significant cross field components which contribute to XP radiation rather than CO radiation. Therefore, with a view to perturb this  $TM_{21}$  mode significantly and  $TM_{11}$  mode partially, first notch is cut on the patch surface of Antenna#2 in the range of  $\phi = 45^\circ$  to  $138^\circ$  which germinates Antenna#3 (Fig. 5.5 (c)). This in turn, suppresses the XP radiations from both the (i) higher order  $TM_{21}$  mode and (ii) orthogonal component of dominant  $TM_{11}$  mode.

To cut this first notch, a circle of radius  $r = 6$  mm has been considered whose centre is at  $(a + s)$  (centered at  $x = 0$ ,  $y = 8$  mm and  $d_c = 4$  mm,  $s = 2$  mm) from the

centre of the patch along 'y' axis as shown in Fig. 5.7. The locus of the circle which cuts the first notch is

$$\left. \begin{aligned} x &= r \cos \psi \\ y &= (a + s) + r \sin \psi \end{aligned} \right\} \quad (5.4)$$

where,  $\psi \rightarrow 0$  to  $\psi \rightarrow -180^\circ$

**Fig. 5.7** Design topology of proposed CSMA surface

The H-plane radiation characteristics of Antenna#1, Antenna#2 and Antenna#3 have been depicted in Fig. 5.8(a) Antenna#2 exhibits broadside XP pattern with XPD of 13 dB at the bore sight whereas, the XPD in CMA (Antenna#1) is better (16 dB at  $\pm 60^\circ$  elevation angle) with conical profile. However, with the introduction of first notch, the XPD starts to improve consistently in Antenna#3. The H-plane radiation profile of Antenna#3 has been depicted in Fig. 5.8(a) as the function of first notch depth  $d_c$ . It shows that, as  $r$  increases,  $d_c$  increases in Antenna#3 and the XPD becomes improved. The maximum XPD is 20-21 dB at  $\pm 60^\circ$  elevation angle with  $d_c = 4$  mm. Around 62% and 40% of improvement in XPD is exposed with Antenna#3 ( $d_c = 4$  mm) compared to Antenna#2 and Antenna#1, respectively. The CO radiation patterns of all three antennas are exactly similar. The simulated gain for Antenna#1, Antenna#2 and Antenna#3 ( $d_c = 4$  mm) are 7.84 dBi, 7.6 dBi and 7.35 dBi respectively. It is observed from Fig. 5.8 (b) that, as  $d_c$  increases from 1 mm to 4 mm, the resonant frequency is decreased by 16% from 8.67 GHz (Antenna#1 and Antenna#2) to 7.43 GHz (Antenna#3 with  $d_c = 4$  mm). Therefore, without much sacrificing it's gain performance, the miniaturization as well as improved XP

(a)

(b)

**Fig. 5.8** (a) The effect of the depth  $d_c$  of first notch on simulated H plane radiation patterns of Antenna#1, Antenna#2, Antenna#3, (b) Simulated resonant frequencies and gain variation as function of  $d_c$ .

suppression can be achieved in Antenna#3. However, no apparent change is noted in E-plane CO and XP radiation and hence we refrain from giving the polarization performance in E-plane. Even though, Antenna#3 exhibits better performances in comparison to Antenna#1, Antenna#2 with respect to miniaturization and XPD, it may be noted that, the XPD at  $-15^\circ$  (i.e., at bore sight and definitely within 3 dB beam width of CO main beam) is 23 dB while the same for Antenna#1 is 24 dB (Fig. 5.8 (a)). In fact, the horizontal component of the fringing field (Fig. 5.9 (a)) along the left truncated edge of Antenna#3 is mainly responsible for the increase in XP radiation near the bore sight (at  $-15^\circ$ ). Recalling Fig. 5.6 (c), the electric field variation of  $TM_{11}$  mode along the radial dimension (Fig. 5.6 (c); green curve) reveals that, the significant amount of field i.e. (40% to 90% of maximum electric field at  $\rho=a$ ) offering cross electric field components of own dominant  $TM_{11}$  mode exist in the range of  $\rho= 1.5$  mm to 4.5 mm in  $180^\circ$  CSMA ( $a =6$  mm, along  $\phi=180^\circ$ ). The electric field vector distribution in the substrate for Antenna#3 (Fig. 5.9 (a)) confirms the observation. Therefore, the second notch is cut on Antenna#3 in this specified region (i.e.,  $\rho = 1.5$  mm to 4.5 mm) to further reduce the XP radiation at bore sight direction.

(a)

**Fig. 5.9** Simulated electric field vector distribution in the substrate at excited dominant  $TM_{11}$  mode (a) Antenna#3, (b) Antenna#4 (proposed).

Notably, the second notch is cut at the upper left edge (opposite side of feed probe) of the patch in Antenna#3 to avoid the spurious radiation from feed probe. To cut this second notch, another circle of radius  $r_1 = 1.5$  mm has been considered whose centre is at  $-a/2$  (centered at  $x = -a/2$ ,  $y = 0$  mm) from the centre of the patch along 'x' axis as shown in Fig. 5.7. The locus of the second notch can be written as  $x = a/2 + r_1 \cos \psi_1$  and  $y = r_1 \sin \psi_1$  where,  $\psi_1 \rightarrow 0$  to  $\psi_1 \rightarrow 180^\circ$

Consequently, the electric field follows the curvature of the notch periphery as is shown in Fig. 5.9 (b). The close inspection of Figs. 5.9 (a) and (b) reveals that, the presence of 2<sup>nd</sup> notch converts some of the cross fields ( $E_y$ ) from the left upper truncated edge of the patch to co-polar fields ( $E_x$ ). This effectively reduces the orthogonal electric field component (from upper left edge of the patch) offering XP radiation near the bore sight direction. In Antenna#4, the XPD is improved significantly and it becomes 28-40 dB (Fig. 5.10 (a) and 5.10 (b)). However, CO gain and radiation profile (7.35 dBi) are exactly similar for all values of  $r_1$ . Also, as  $r_1$  increases, the resonant frequency decreases further from 7.43 GHz (Antenna#3) to 7.22 GHz (Antenna#4). The resonant frequencies and XPD at  $-60^\circ$  and  $-15^\circ$  elevation angle is portrayed in Fig. 5.10 (b) establishes the superiority of the Antenna#4 (with  $d_c = 4$  mm and  $r_1 = 1.5$  mm) over Antenna#1, #2 and #3 in relation to the miniaturization and improvement in XPD.

(a)

(b)

**Fig. 5.10** The effect of the depth  $r_l$  of second notch on (a) H plane radiation patterns of Antenna#3, (b) resonant frequencies and XPD as function of  $r_l$ .

It may be noted that, two notches at the patch surface effectively modulates the locus of surface current paths in such a way that, the orthogonal current component

reduces. The electric surface current on patch surface of Antenna#2 at  $TM_{11}$  mode follows the longitudinal path with a curvature (current lines are tilted; Fig. 5.11(a) and Fig. 5.11 (b) while flowing from lower to upper section of the patch. Therefore, the horizontal current components (red) due to tilted current lines (Fig. 5.11(b)) contribute in XP radiation.

(a)

(b)

**Fig. 5.11** The electric surface current over the patch surface (a) simulated (Antenna#2), (b) schematic (Antenna#2).

(a)

(b)

**Fig. 5.12** The electric surface current over the patch surface(a) simulated (Antenna#3), (b) schematic (Antenna#3).

**Fig. 5.13** The electric surface current over the patch surface (a) simulated (Antenna#4), (b) schematic (Antenna#4).

Contrarily, due to the presence of first notch in Antenna#3, the horizontal current components in lower and upper half sections of the patch cancel each other as is explained in Fig. 5.12 (a) and Fig. 5.12 (b). Therefore, the effects of horizontal current component near patch periphery can be controlled to reduce the XP radiation and also to achieve nearly conical pattern instead of broadside. Notably, some electric surface currents near the central region of the patch still exist that leaves

some horizontal current component. Hence, in Antenna#4, a second small notch is cut at the upper side of the patch along  $\phi = 180^\circ$  as shown in Fig. 5.13. This effectively reduces the horizontal electric current components more on the patch surface of Antenna#4, as is explained in Fig. 5.13 (a) and Fig. 5.11 (b).

## 5.6 Proposed Structure

First, a semicircular CSMA (with  $\phi_0=180^\circ$ ) having radius  $a = 6$  mm has been fabricated with copper strip (0.5 mm thickness) on RT-5870 ( $\epsilon_r=2.33$  and thickness  $h = 1.575$  mm) substrate. First, the dimensions of substrate and ground plane are chosen to be  $60 \text{ mm} \times 60 \text{ mm}$  ( $\sim 1.4\lambda_0 \times 1.4\lambda_0$ ). First notch is cut on the patch with  $d_c = 4\text{mm}$  (i.e.  $r = 6$  mm,  $s = 2$  mm) (Fig. 5.7). The second notch is cut on the patch at the opposite side with a circular locus (centered at  $a/2 = 3$  mm) of  $r_l = 1.5$  mm, as described in Fig. 5.7. The patch is fed at 0.8 mm from the centre point (Fig. 5.4). Further, the same structure is fabricated on small ground plane ( $28 \text{ mm} \times 28 \text{ mm}$  or  $\sim 0.66\lambda_0 \times 0.66\lambda_0$ ). Moreover, the structure has been fabricated on very small ground plane ( $14 \text{ mm} \times 14 \text{ mm}$  or  $\sim 0.33\lambda_0 \times 0.33\lambda_0$ ) to be considered as small antenna as this whole antenna (including ground plane) can be enclosed within a sphere where  $k.R < 1$ .

## 5.7 Results and Discussions

The reference Antenna#1 of 7 mm radius has also been fabricated on same substrate with  $60 \text{ mm} \times 60 \text{ mm}$  ground plane. In Fig. 5.14 (a), the measured reflection coefficient profiles for the proposed Antenna#4 and the reference CMA (Antenna#1) are presented. Both the antennas resonate near 7.22 GHz with almost similar impedance bandwidth. In the E-plane, the XPD is more than 30 dB for both Antenna#1 and Antenna#4 (Fig. 5.14 (b)). The measured CO gain of Antenna#1 and Antenna#4 are 7.4 dBi and 7.1 dBi, respectively. The Fig. 5.13 (a) reveals that the XPD of the Antenan#4 (designed over large ground plane) is around 25 dB over entire elevation angle near the bore sight in H-plane whereas; the same for Antenna#1 is only 15 dB. For further corroboration of the validity of the results for the Antenna#4, the complete radiation pattern has been examined on smaller ( $28 \text{ mm} \times 28 \text{ mm}$ ) (resonating at 7.17 GHz) and very small ( $14 \text{ mm} \times 14 \text{ mm}$ ) (resonating at

7.21 GHz) ground planes (Fig. 5.15 (b), Fig. 5.16(a)). Both the structures reveal symmetry in E and H-plane CO radiation patterns with consistent and more than

**Fig. 5.14** Measured results for (a) reflection coefficient profiles, (b) comparison of E plane radiation patterns for reference CMA and proposed antenna over large (60 mm  $\times$  60 mm) ground plane.

(a)

(b)

**Fig. 5.15** (a) Comparison of H plane radiation patterns for reference CMA and proposed antenna over large (60 mm × 60 mm) ground plane, (b) measured E and H plane radiation patterns for proposed antenna over medium/small (28 mm × 28 mm) ground.

**Fig. 5.16** (a) Measured E and H plane radiation patterns for proposed antenna over very small (14 mmx14 mm) ground plane, (b) variation of CO gain and XPD as a function of ground plane dimension of proposed antenna.

25 dB of XPD in H-plane with around 5 dBi gain. The measured efficiencies of the proposed antenna over large and very small ground planes are 82% and 68%, respectively.

Notably, the reference antenna (Antenna#1) with larger radius has the efficiency of 86%. The measured gain and XPD variation of the proposed antenna as function of ground plane size is depicted in Fig. 5.16 (b). As the ground plane size reduces, the gain reduces, and E plane beamwidth becomes narrow while H plane beamwidth becomes broad [30]. Therefore, smaller ground plane brings symmetry in E and H plane radiation patterns and hence, XPD improves [30], However, gain to directivity ratio decreases and hence efficiency decreases. The performance of the Antenna#4 has been compared with the available relevant literatures in Table 5.1. This confirms the consistency and superiority of the present structure over others.

## 5.8 Conclusion

A compact semicircular CSMA has been investigated thoroughly and is found to be a better alternative of conventional CMA. Although small, the radiation characteristic of the present antenna is even far better than the conventional CMA geometry which find potential applications. The present antenna works very well on very small ground plane and may be treated as small antenna.

## Conclusion and Scope for Future Studies

In the dissertation, the various issues of circular sector microstrip antenna (CSMA) has been investigated thoroughly in the light of clear physical insight as well as experiments. Some very critical and important issues of CSMA has been studied and documented which will be helpful for scientific and research community. CSMA is advantageous and most useful as it requires less space compare to all other conventional structure like rectangular & circular as is discussed in chapter 1. These CSMA's with individual sector angle has different unique input and radiation features. In fact, different sector angle of CSMA excites different fundamental and higher order modes. Therefore, CSMA has unique feature to excite numerous numbers of fundamental modes based on its sector angle. Therefore, scientific and research community is in urgent need of thorough and methodological study on the determination of fundamental mode and its frequency.

To alleviate the lacuna of earlier studies, a modified cavity model has been developed to determine the fundamental mode and its resonant frequency in chapter 2. The modal fields of the dominant as well as higher order modes of numerous CSMA's with different sector angles have been thoroughly studied. In this chapter 2, an improved, accurate and comprehensive computer-aided design formulation for accurately determining the resonant frequency of a CSMA has been proposed. The proposed formulation accurately estimates the dominant and higher mode resonances in a CSMA with and without an air gap between the substrate and the ground plane. No published work that presents the variation of the resonant frequency of a CSMA with substrate thickness, air gap height, substrate permittivity, and the radial

dimension of the antenna is available till date. Considering all the above-mentioned factors, the resulting variations of resonant frequencies as a function of the aforementioned parameters, have been included in the present study. An improved formulation of Computer aided design (CAD) has been proposed for easy prediction of exact resonance frequency of CSMA without much effort to the rigorous simulation. The propose CAD formulation exhibits much improved and provides more accurate result in relation to simulated and measured result.

Chapter 3 deals with the excitation of desired modes in a circular sector microstrip antenna (CSMA) as a function of feed location. The key influence of the feed-probe position in exciting particular mode has been thoroughly studied. Also, the investigation has been done for wide range of sector angles. The proposed theory has been validated through simulation as well as experiments. Excellent agreement is reveled amongst theoretical prediction, simulation and measurements. An accurate but quick hand approximate theoretical technique has been developed to determine the feed location of a CSMA which can excite a specific mode based on  $E/H$  ratio. The gain of the antenna has also been analyzed and enhanced by incorporations the air instead of conventional substrate. The comparative study using air and PTFE substrate for identical patch has been investigated to estimate the gain enhancement of a particular sector angle. An easy and a quick hand formulation is developed to determine the gain enhancement of CSMA with air substrate in comparison to conventional PTFE substrate. This easy technique will be surely be helpful for scientist and practicing engineers looking for designing CSMA's.

As such, CSMA of different sector angles have entirely different characteristics and hence, suitable choice of sector angle is very critical to design CSMA with optimum performance. Therefore, a compact design guideline of CSMA has been documented in chapter 4. Thorough design opportunities and limitations are presented in this chapter. In fact, the comprehensive design guidelines provided in chapter 4 will be very much beneficial for future designers to estimate best possible configuration for any specified application. Based on design guidelines, prototypes are fabricated, measured and compared with conventional circular patch. This reveals that  $170^\circ$  to  $180^\circ$  CSMA has better performance in comparison to classical circular patch.

Based on theories developed in chapter 2 to 4, a semicircular patch with defected patch surface approach has been developed for much improved radiation characteristics in comparison to conventional CMA in chapter 5. However, in course of investigation, it is observed that the cross polarization of such antennas with  $170^0$  to  $180^0$  sector angles are comparatively high with respect to CMA. Therefore, in chapter 5, the cross polarization of  $180^0$  CSMA has been minimized a new technique called defected the patch surface approach. This can be done by judiciously cutting the notch on the patch surface. In addition with that, the ground plane dimension has also been investigated to see the effect on ground plane dimension on new antenna characteristics. Notably, the designed antenna worked well as very small ground plane and can be designated as small antenna.

The investigation on theoretical and experimental study has been presented in this dissertation which is important for commercial and engineering applications, along with research and future application.

The investigation documented in this dissertation germinates a plentiful opportunity of CSMA over other geometries. CSMA with different sector angles have different excitation mode and hence they have different radiation performance. Therefore, some other investigation may also be carried out individually for individual sector angles. Improved radiation performance in comparison to CMA has been established with DPS loaded  $180^0$  CSMA. Hence, other CSMA angles may also be explored to yield more improved radiation characteristics of CSMA in comparison to CMA. Broad banding or dual banding of CSMA may also be explored based on theory developed in chapter 2 to chapter 4.

# Design Approach Toward Compact Circular Sector Microstrip Antenna With Low Cross Polarization

Sudip K. Ghosh , Abhijyoti Ghosh , Subhradeep Chakraborty, *Member, IEEE*, L. Lolit K. Singh, and Sudipta Chattopadhyay , *Member, IEEE*

**Abstract**—In this letter, a novel and compact  $180^\circ$  circular sector microstrip antenna has been proposed. The patch surface has been designed with a proper design insight to perturb and control the orthogonal surface current paths and orthogonal field components at the truncated edges for suppression of cross-polar (XP) radiations over the whole elevation without hampering its radiation pattern and bandwidth. The proposed antenna gives consistently better performance with different (large, medium, and small) ground plane sizes in spite of massive miniaturization (of 82%) with reference to conventional circular microstrip antenna at the same frequency. The proposed antenna can also be circumscribed completely within a sphere of radius  $(\lambda/2\pi)$ , i.e., wheeler limit and hence can stand well as a small antenna.

**Index Terms**—Circular sector microstrip antenna, cross-polarized radiation, radiation characteristics.

## I. INTRODUCTION

IN RECENT years, there is an increased surge in exploring and enhancing the characteristics of tiny antennas, which can be implemented in the limited available spaces in miniaturized compact wireless communication device without hampering the antenna performance. In this perspective, circular sector microstrip antenna (CSMA) with relatively smaller sector angle ( $\phi_0 = 180^\circ$ ) is an excellent preference over circular microstrip antenna (CMA) [1]–[4]. Earlier, rectangular microstrip antenna (RMA) and CMA were widely investigated for patch area miniaturization in [5]–[15]. However, such miniaturized antennas suffer from very poor gain [11], bandwidth [9]–[11], and high cross-polar (XP) radiations [9]–[12], squinted E-plane dipole like profile and omnidirectional H-plane profile [13]. CSMA with very large sector angles, i.e.,  $\phi_0 \sim 270^\circ$ ,  $340^\circ$ , and  $350^\circ$  have been investigated in [16]–[18] for broad banding or multi-banding without any improvement in radiation performance or miniaturization. Further, Ghosh *et al.* [19] shows that  $180^\circ$  CSMA offers poor copolar (CO) to cross-polar radiation (XP) isolation (XPD) (around 8 dB) at the X-band with a broadside XP pattern instead of a conical XP pattern which affects the

Fig. 1. (a) Schematic representation of proposed antenna (top view) and (b) fabricated prototypes over large and smaller ground planes.

main CO profile. Therefore, it is undeniably challenging to modulate the XP profile of  $180^\circ$  CSMA with improved XPD along with achieving miniaturization. It is well-known that linearly polarized CMA and RMA exhibit high XP radiations [1], [4], [20]–[27]. However, common XP radiation minimization techniques for instance, use of modified feed structures, defected ground structures (DGSs), and shorted patch and pins (SP); have not been investigated till date for minimizing XP radiations in CSMA with small sector angle ( $\phi_0 \rightarrow 180^\circ$ ). Notably, a CSMA with sector angle  $\phi_0 = 180^\circ$  has a thought-provoking feature of exciting similar dominant mode and resonant frequency in comparison with that of a conventional CMA with around 50% patch area reduction. Also, the ground plane dimension becomes a parameter of vital relevance to designing of miniaturized antenna [28]. Most of earlier reported structures could not show their efficacy as small antenna by circumscribing the patch radiator (including ground plane) within a sphere of radius  $(\lambda/2\pi)$ , i.e., Wheeler limit.

Therefore, in this letter, a compact CSMA (with  $\phi_0 = 180^\circ$ ) structure has been proposed, (see Fig. 1) with improved radiation characteristics, low XP radiation along with miniaturization. Further, the proposed structure exhibits satisfactory performance on very small ground plane also.

## II. EVOLUTION ANALYSIS OF THE PROPOSED ANTENNA

First, a CMA with radius  $a$  was designed over the substrate ( $\epsilon_r = 2.33$ , thickness  $h = 1.575$  mm) at X-band that acts as a reference CMA (Antenna#1) [see Fig. 2(a)]. In step 2, the left half of the patch surface was removed which gave birth to a CSMA with  $\phi_0 = 180^\circ$  (Antenna#2) as shown in Fig. 2(b). The parametric equation for the locus of Antenna#2 can be written as

$$x = a \cos \phi \text{ and } y = a \sin \phi \quad (1)$$

where  $\phi \rightarrow 0$  to  $\phi \rightarrow 180^\circ$  ( $\phi_0$ ) and  $a = 6$  mm

# The Influence of Feed Probes on the Modes of Circular Sector Microstrip Antennas

*An investigation.*

In this article, the key influence of the feed-probe position for the excitation of desired modes in a circular sector microstrip antenna (CSMA) is thoroughly investigated via physical analysis comprising simulations and measurements. The approximate feed location used to excite a particular mode is also empirically determined to facilitate further exploration of CSMA. Based on the proposed analysis and simulations, CSMA with a wide range of sector angles are studied, and good agreements are revealed when compared with the measurements.

## INTRODUCTION

In recent years, there has been increased attention toward exploring and enhancing the radiation and input characteristics of circular sector microstrip antenna (CSMA) for modern applications due to its conformality over curved surfaces and better compactness compared to other regularly shaped patch geometries, i.e., rectangular and circular. Aside from applying a circularly polarized CSMA (see [1]), recently, other significant works on wideband and multiband CSMA have been reported in [2]–[6]. Notably, all of these investigations were initiated by applying appropriate

## Abstract

Determination of accurate modal fields is one of the most crucial issues to understand the proper behavior of circular sector microstrip antennas (CSMAs) to achieve the best performance. In this article, dominant and higher order modal characteristics have been rigorously studied which germinate an improved, accurate, and efficient computer-aided design (CAD) formulation to estimate the resonant frequency of CSMA with and without air gap between substrate and ground plane. The proposed formulation can address the wide variety of issues (such as substrate height, substrate permittivity, air gap height, higher order modes, etc.). The computed results were validated against the results obtained from high-frequency structure simulator (HFSS) and our own experiments, while they have been also justified through the results obtained from the available literature.

antenna parameters, circular sector, microstrip antenna, resonant frequency

## 1 | INTRODUCTION

IN the modern era of microwave communications, the design and analysis of miniaturized and multifunctional antennas of different geometries continue to be the focus of state-of-the-art research. In this scenario, microstrip patch antennas (MPAs) are extremely useful and are the obvious choice of the designers because of their light weight, small size, and excellent compatibility with monolithic microwave integrated circuits. The most common geometries of MPAs, such as rectangular and circular, have been extensively studied, analyzed, and implemented for at least the last three decades. In fact, a significant number of analyses<sup>1–6</sup> and applications<sup>7–12</sup> of common MPA geometries have been reported during the last two decades. However, in various practical wireless applications, radiators should be conformally mounted onto the previously existing structures, where space limitation is a crucial problem. In such applications, a circular sector microstrip antenna (CSMA) is highly advantageous because it requires

less space than a conventional patch antenna of common geometries. Approximately 30% and 35% patch area reductions can be achieved with a CSMA using 60° and 90° sector angles, respectively, compared with a conventional circular MPA. Therefore, an accurate analysis of CSMA is a priority in the present scenario of printed antenna research. In this context, we have found a limited number of analyses,<sup>13–17</sup> in which the computation of the accurate resonant frequency of CSMA with arbitrary sector angles has been dealt with.

The formulation of the resonant frequency of a CSMA based on the cavity model was first reported in ref. 13. The electric field beneath the patch and the eigen functions of those antennas were also presented in ref. 13. In ref. 14, a generalized transmission line modeling was used for computing the resonant frequency of a CSMA. However, the effect of fringing fields, which should be considered for the accurate estimation of the resonant frequency of a CSMA, was not included in refs. 13 and 14.

In partial fulfillment of the requirement of the Degree of Doctor of Philosophy in  
Electronics and Communication Engineering of Mizoram University, Aizawl

In this modern era, the scientific and research community looking for a miniaturized antenna structure other than conventional circular microstrip antenna geometry. This is very much helpful for modern wireless industries to develop miniaturized hand-held wireless communication equipments. In this stage, circular sector microstrip antenna is highly applicable as it requires less patch size compare to other conventional geometry. In this dissertation, one of the miniaturized and versatile antenna structures, named circular sector microstrip antenna (CSMA) has been broadly investigated. Which can be derived from circular microstrip antenna (CMA) structure by cutting a sector angle. In comparison to the conventional circular patch geometries, the CSMA is hardly explored by researchers till date. Therefore, to implement such CSMA in different applications, it is imperative to investigate its basic input, radiation characteristics and the modal behavior along with miniaturization.

So, the determination of the lowest order dominant mode of CSMA is the most vital and primary focus to explore CSMA characteristics. In this context, the modal behavior of such antenna is not analyzed elaborately in available literatures and reported design formulations also fail to predict accurate resonant frequencies of CSMA with different sector angle. Accurate dominant mode for CSMA with arbitrary sector angle is not clear and based on simulation only. Simple theoretical design formulas are still important to estimate the operating frequency before run any simulator. Accurate theoretical formulas are very much required from application point of view. Therefore, the structure has not been studied methodically till date.

The modal analysis of dominant and higher order mode of different sector angles has been thoroughly studied using modified cavity model. Computer aided theoretical formulation (CAD) has been developed for accurate determination of dominant mode and higher order mode (HOM) in chapter 2. The modal fields of the dominant as well as higher order modes of numerous CSMA with different sector angles have been thoroughly studied. In this chapter 2, an improved, accurate and comprehensive computer-aided design formulation for accurately determining the resonant frequency of a CSMA has been proposed. The proposed formulation accurately estimates the dominant and higher mode resonances in a CSMA with and without an air gap between the substrate and the ground plane. No published work

that presents the variation of the resonant frequency of a CSMA with substrate thickness, air gap height, substrate permittivity, and the radial dimension of the antenna is available till date. Considering all the above-mentioned factors, the resulting variations of resonant frequencies as a function of the aforementioned parameters, have been included in the present study.

The accurate estimation of the feed-probe position for the excitation of desired modes in a circular sector microstrip antenna (CSMA) is also another basic design requirement. Moreover, optimization of feed positions for the excitation of dominant modes is very essential to obtain the optimum performance of CSMA. Therefore, effect of feed probe location on the excitation of a particular mode (lowest order dominant and HOMs) has been thoroughly studied in chapter 3. Infact, different modes can be excited with CSMA of different angles based on different feed locations. Correspondingly, radiation characteristics changes for a particular CSMA. Even polarization of radiation fields also changes due to feed probe location. Modal behavior of different excited electromagnetic modes in CSMA as a function of feed-probe position is not analyzed elaborately in available literatures. Therefore, to identify the feed location for excitation of particular mode in CSMA for a wide variety of sector angles a simple, quick hand & accurate technique has been carried out. The estimation of the suitable range of feeding position has been thoroughly investigated and quick hand and accurate technique is proposed in chapter 3. The modal fields of the dominant as well as higher order modes of numerous CSMA with different sector angles have been thoroughly studied in chapter 3. The new theoretical approximation technique has been derived based on  $E/H$  ratio beneath the patch to excite a specific mode. Indeed, CSMA with different range of sector angles has been classified and discussed scientifically by the relation of  $E/H$  ratio. A particular range of  $|E/H|$  has been recommended on which a particular mode can be excited. Moreover, a range of feed location has been approximated across which a particular mode can be excited if probe is placed. Hence, the present investigation will be surely helpful to the scientific community to germinate new ideas related to the excitation of modes with desirable polarizations as a function of feed-probe location for practical applications. Previous two chapters, the investigation has been carried out only of input characteristics. So, the radiation characteristics and gain of

this antenna have been given equal importance to explore the performance of the antenna in large extent. The Gain of this antenna is generally 7.1 dBi that has been improved to 9.9 dBi by introduction an air substrate. The quick hand formula has been developed for calculating the enhancement of gain of CSMA with air substrate in comparison to conventional substrate.

In chapter 4, the complete design guideline has been prescribed for the specific application. The behavior of CSMA is generally varied with sector angles due to its different type of geometry. Thus, selection of sector angles in terms of operating mode, frequency and miniaturization has been thoroughly studied for better selection of CSMA angles. A compact and comprehensive guideline has been prescribed documented in chapter 4.

In chapter 5, CSMA of  $180^\circ$  sector angle has been considered based on an earlier investigation documented in chapter 3 to chapter 4. An investigation in view of the replacement of CMA with  $180^\circ$  CSMA has been successfully proposed. The minimization of patch area is always advantageous and around 82% miniaturization has been achieved in comparison to conventional CMA exciting the particular dominant mode. In order to improve the polarization purity, the patch area has been defected judiciously. The proposed antenna in chapter 5, works on very small ground plane and satisfactory radiation performance is revealed.

The thorough investigation presented in this dissertation is most up to date with cutting edge technologies and complete in all aspects and hence should be very much helpful for efficient CSMA design.
